

As shown, the computer system 50 includes a processor 56 configured to execute instructions and to carry out operations associated with the computer system 50. For example, using instructions retrieved for example from memory, the processor 56 may control the reception and manipulation of input and output data between components of the computing system 50. The processor 56 can be a single-chip processor or can be implemented with multiple components.

In most cases, the processor 56 together with an operating system operates to execute computer code and produce and use data. The computer code and data may reside within a program storage block 58 that is operatively coupled to the processor 56. Program storage block 58 generally provides a place to hold data that is being used by the computer system 50. By way of example, the program storage block may include Read-Only Memory (ROM) 60, Random-Access Memory (RAM) 62, hard disk drive 64 and/or the like. The computer code and data could also reside on a removable storage medium and loaded or installed onto the computer system when needed. Removable storage mediums include, for example, CD-ROM, PC-CARD, floppy disk, magnetic tape, and a network component.

The computer system 50 also includes an input/output (I/O) controller 66 that is operatively coupled to the processor 56. The I/O controller 66 may be integrated with the processor 56 or it may be a separate component as shown. The I/O controller 66 is generally configured to control interactions with one or more I/O devices. The I/O controller 66 generally operates by exchanging data between the processor and the I/O devices that desire to communicate with the processor. The I/O devices and the I/O controller typically communicate through a data link 67. The data link 67 may be a one way link or two way link. In some cases, the I/O devices may be connected to the I/O controller 66 through wired connections. In other cases, the I/O devices may be connected to the I/O controller 66 through wireless connections. By way of example, the data link 67 may correspond to PS/2, USB, Firewire, IR, RF, Bluetooth or the like.

The computer system 50 also includes a display device 68 that is operatively coupled to the processor 56. The display device 68 may be a separate component (peripheral device) or it may be integrated with the processor and program storage to form a desktop computer (all in one machine), a laptop, handheld or tablet or the like. The display device 68 is configured to display a graphical user interface (GUI) including perhaps a pointer or cursor as well as other information to the user. By way of example, the display device 68 may be a monochrome display, color graphics adapter (CGA) display, enhanced graphics adapter (EGA) display, variable-graphics-array (VGA) display, super VGA display, liquid crystal display (e.g., active matrix, passive matrix and the like), cathode ray tube (CRT), plasma displays and the like.

The computer system 50 also includes a touch screen 70 that is operatively coupled to the processor 56. The touch screen 70 is a transparent panel that is positioned in front of the display device 68. The touch screen 70 may be integrated with the display device 68 or it may be a separate component. The touch screen 70 is configured to receive input from a user's touch and to send this information to the processor 56. In most cases, the touch screen 70 recognizes touches and the position and magnitude of touches on its surface. The touch screen 70 reports the touches to the processor 56 and the processor 56 interprets the touches in accordance with its programming. For example, the processor 56 may initiate a task in accordance with a particular touch.

In accordance with one embodiment, the touch screen 70 is capable of tracking multiple objects, which rest on, tap on, or

move across the touch sensitive surface of the touch screen at the same time. The multiple objects may for example correspond to fingers and palms. Because the touch screen is capable of tracking multiple objects, a user may perform several touch initiated tasks at the same time. For example, the user may select an onscreen button with one finger, while moving a cursor with another finger. In addition, a user may move a scroll bar with one finger while selecting an item from a menu with another finger. Furthermore, a first object may be dragged with one finger while a second object may be dragged with another finger. Moreover, gesturing may be performed with more than one finger.

To elaborate, the touch screen 70 generally includes a sensing device 72 configured to detect an object in close proximity thereto and/or the pressure exerted thereon. The sensing device 72 may be widely varied. In one particular embodiment, the sensing device 72 is divided into several independent and spatially distinct sensing points, nodes or regions 74 that are positioned throughout the touch screen 70. The sensing points 74, which are typically hidden from view, are dispersed about the touch screen 70 with each sensing point 74 representing a different position on the surface of the touch screen 70 (or touch screen plane). The sensing points 74 may be positioned in a grid or a pixel array where each pixelated sensing point 74 is capable of generating a signal at the same time. In the simplest case, a signal is produced each time an object is positioned over a sensing point 74. When an object is placed over multiple sensing points 74 or when the object is moved between or over multiple sensing point 74, multiple signals are generated.

The number and configuration of the sensing points 74 may be widely varied. The number of sensing points 74 generally depends on the desired sensitivity as well as the desired transparency of the touch screen 70. More nodes or sensing points generally increases sensitivity, but reduces transparency (and vice versa). With regards to configuration, the sensing points 74 generally map the touch screen plane into a coordinate system such as a Cartesian coordinate system, a Polar coordinate system or some other coordinate system. When a Cartesian coordinate system is used (as shown), the sensing points 74 typically correspond to x and y coordinates. When a Polar coordinate system is used, the sensing points typically correspond to radial (r) and angular coordinates (θ).

The touch screen 70 may include a sensing circuit 76 that acquires the data from the sensing device 72 and that supplies the acquired data to the processor 56. Alternatively, the processor may include this functionality. In one embodiment, the sensing circuit 76 is configured to send raw data to the processor 56 so that the processor 56 processes the raw data. For example, the processor 56 receives data from the sensing circuit 76 and then determines how the data is to be used within the computer system 50. The data may include the coordinates of each sensing point 74 as well as the pressure exerted on each sensing point 74. In another embodiment, the sensing circuit 76 is configured to process the raw data itself. That is, the sensing circuit 76 reads the pulses from the sensing points 74 and turns them into data that the processor 56 can understand. The sensing circuit 76 may perform filtering and/or conversion processes. Filtering processes are typically implemented to reduce a busy data stream so that the processor 56 is not overloaded with redundant or non-essential data. The conversion processes may be implemented to adjust the raw data before sending or reporting them to the processor 56. The conversions may include determining the center point for each touch region (e.g., centroid).

The sensing circuit 76 may include a storage element for storing a touch screen program, which is a capable of con-

trolling different aspects of the touch screen 70. For example, the touch screen program may contain what type of value to output based on the sensing points 74 selected (e.g., coordinates). In fact, the sensing circuit in conjunction with the touch screen program may follow a predetermined communication protocol. As is generally well known, communication protocols are a set of rules and procedures for exchanging data between two devices. Communication protocols typically transmit information in data blocks or packets that contain the data to be transmitted, the data required to direct the packet to its destination, and the data that corrects errors that occur along the way. By way of example, the sensing circuit may place the data in a HID format (Human Interface Device).

The sensing circuit 76 generally includes one or more microcontrollers, each of which monitors one or more sensing points 74. The microcontrollers may for example correspond to an application specific integrated circuit (ASIC), which works with firmware to monitor the signals from the sensing device 72 and to process the monitored signals and to report this information to the processor 56.

In accordance with one embodiment, the sensing device 72 is based on capacitance. As should be appreciated, whenever two electrically conductive members come close to one another without actually touching, their electric fields interact to form capacitance. In most cases, the first electrically conductive member is a sensing point 74 and the second electrically conductive member is an object 80 such as a finger. As the object 80 approaches the surface of the touch screen 70, a tiny capacitance forms between the object 80 and the sensing points 74 in close proximity to the object 80. By detecting changes in capacitance at each of the sensing points 74 and noting the position of the sensing points, the sensing circuit can recognize multiple objects, and determine the location, pressure, direction, speed and acceleration of the objects 80 as they are moved across the touch screen 70. For example, the sensing circuit can determine when and where each of the fingers and palm of one or more hands are touching as well as the pressure being exerted by the finger and palm of the hand(s) at the same time.

The simplicity of capacitance allows for a great deal of flexibility in design and construction of the sensing device 72. By way of example, the sensing device 72 may be based on self capacitance or mutual capacitance. In self capacitance, each of the sensing points 74 is provided by an individual charged electrode. As an object approaches the surface of the touch screen 70, the object capacitively couples to those electrodes in close proximity to the object thereby stealing charge away from the electrodes. The amount of charge in each of the electrodes are measured by the sensing circuit 76 to determine the positions of multiple objects when they touch the touch screen 70. In mutual capacitance, the sensing device 72 includes a two layer grid of spatially separated lines or wires. In the simplest case, the upper layer includes lines in rows while the lower layer includes lines in columns (e.g., orthogonal). The sensing points 74 are provided at the intersections of the rows and columns. During operation, the rows are charged and the charge capacitively couples to the columns at the intersection. As an object approaches the surface of the touch screen, the object capacitively couples to the rows at the intersections in close proximity to the object thereby stealing charge away from the rows and therefore the columns as well. The amount of charge in each of the columns is measured by the sensing circuit 76 to determine the positions of multiple objects when they touch the touch screen 70.

FIG. 6 is a partial top view of a transparent multiple point touch screen 100, in accordance with one embodiment of the

present invention. By way of example, the touch screen 100 may generally correspond to the touch screen shown in FIGS. 2 and 4. The multipoint touch screen 100 is capable of sensing the position and the pressure of multiple objects at the same time. This particular touch screen 100 is based on self capacitance and thus it includes a plurality of transparent capacitive sensing electrodes 102, which each represent different coordinates in the plane of the touch screen 100. The electrodes 102 are configured to receive capacitive input from one or more objects touching the touch screen 100 in the vicinity of the electrodes 102. When an object is proximate an electrode 102, the object steals charge thereby affecting the capacitance at the electrode 102. The electrodes 102 are connected to a capacitive sensing circuit 104 through traces 106 that are positioned in the gaps 108 found between the spaced apart electrodes 102. The electrodes 102 are spaced apart in order to electrically isolate them from each other as well as to provide a space for separately routing the sense traces 106. The gap 108 is preferably made small so as to maximize the sensing area and to minimize optical differences between the space and the transparent electrodes.

As shown, the sense traces 106 are routed from each electrode 102 to the sides of the touch screen 100 where they are connected to the capacitive sensing circuit 104. The capacitive sensing circuit 104 includes one or more sensor ICs 110 that measure the capacitance at each electrode 102 and that reports its findings or some form thereof to a host controller. The sensor ICs 110 may for example convert the analog capacitive signals to digital data and thereafter transmit the digital data over a serial bus to a host controller. Any number of sensor ICs may be used. For example, a single chip may be used for all electrodes, or multiple chips may be used for a single or group of electrodes. In most cases, the sensor ICs 110 report tracking signals, which are a function of both the position of the electrode 102 and the intensity of the capacitance at the electrode 102.

The electrodes 102, traces 106 and sensing circuit 104 are generally disposed on an optical transmissive member 112. In most cases, the optically transmissive member 112 is formed from a clear material such as glass or plastic. The electrode 102 and traces 106 may be placed on the member 112 using any suitable patterning technique including for example, deposition, etching, printing and the like. The electrodes 102 and sense traces 106 can be made from any suitable transparent conductive material. By way of example, the electrodes 102 and traces 106 may be formed from indium tin oxide (ITO). In addition, the sensor ICs 110 of the sensing circuit 104 can be electrically coupled to the traces 106 using any suitable techniques. In one implementation, the sensor ICs 110 are placed directly on the member 112 (flip chip). In another implementation, a flex circuit is bonded to the member 112, and the sensor ICs 110 are attached to the flex circuit. In yet another implementation, a flex circuit is bonded to the member 112, a PCB is bonded to the flex circuit and the sensor ICs 110 are attached to the PCB. The sensor ICs may for example be capacitance sensing ICs such as those manufactured by Synaptics of San Jose, Calif., Fingerworks of Newark, Del. or Alps of San Jose, Calif.

The distribution of the electrodes 102 may be widely varied. For example, the electrodes 102 may be positioned almost anywhere in the plane of the touch screen 100. The electrodes 102 may be positioned randomly or in a particular pattern about the touch screen 100. With regards to the later, the position of the electrodes 102 may depend on the coordinate system used. For example, the electrodes 102 may be placed in an array of rows and columns for Cartesian coordinates or an array of concentric and radial segments for polar

coordinates. Within each array, the rows, columns, concentric or radial segments may be stacked uniformly relative to the others or they may be staggered or offset relative to the others. Additionally, within each row or column, or within each concentric or radial segment, the electrodes 102 may be staggered or offset relative to an adjacent electrode 102.

Furthermore, the electrodes 102 may be formed from almost any shape whether simple (e.g., squares, circles, ovals, triangles, rectangles, polygons, and the like) or complex (e.g., random shapes). Further still, the shape of the electrodes 102 may have identical shapes or they may have different shapes. For example, one set of electrodes 102 may have a first shape while a second set of electrodes 102 may have a second shape that is different than the first shape. The shapes are generally chosen to maximize the sensing area and to minimize optical differences between the gaps and the transparent electrodes.

In addition, the size of the electrodes 102 may vary according to the specific needs of each device. In some cases, the size of the electrodes 102 corresponds to about the size of a finger tip. For example, the size of the electrodes 102 may be on the order of 4-5 mm². In other cases, the size of the electrodes 102 are smaller than the size of the finger tip so as to improve resolution of the touch screen 100 (the finger can influence two or more electrodes at any one time thereby enabling interpolation). Like the shapes, the size of the electrodes 102 may be identical or they may be different. For example, one set of electrodes 102 may be larger than another set of electrodes 102. Moreover, any number of electrodes 102 may be used. The number of electrodes 102 is typically determined by the size of the touch screen 100 as well as the size of each electrode 102. In most cases, it would be desirable to increase the number of electrodes 102 so as to provide higher resolution, i.e., more information can be used for such things as acceleration.

Although the sense traces 106 can be routed a variety of ways, they are typically routed in manner that reduces the distance they have to travel between their electrode 102 and the sensor circuit 104, and that reduces the size of the gaps 108 found between adjacent electrodes 102. The width of the sense traces 106 are also widely varied. The widths are generally determined by the amount of charge being distributed there through, the number of adjacent traces 106, and the size of the gap 108 through which they travel. It is generally desirable to maximize the widths of adjacent traces 106 in order to maximize the coverage inside the gaps 108 thereby creating a more uniform optical appearance.

In the illustrated embodiment, the electrodes 102 are positioned in a pixilated array. As shown, the electrodes 102 are positioned in rows 116 that extend to and from the sides of the touch screen 100. Within each row 116, the identical electrodes 102 are spaced apart and positioned laterally relative to one another (e.g., juxtaposed). Furthermore, the rows 116 are stacked on top of each other thereby forming the pixilated array. The sense traces 106 are routed in the gaps 108 formed between adjacent rows 116. The sense traces 106 for each row are routed in two different directions. The sense traces 106 on one side of the row 116 are routed to a sensor IC 110 located on the left side and the sense traces 106 on the other side of the row 116 are routed to another sensor IC 110 located on the right side of the touch screen 100. This is done to minimize the gap 108 formed between rows 116. The gap 108 may for example be held to about 20 microns. As should be appreciated, the spaces between the traces can stack thereby creating a large gap between electrodes. If routed to one side, the size of the space would be substantially doubled thereby reducing the resolution of the touch screen. Moreover, the shape of the

electrode 102 is in the form of a parallelogram, and more particularly a parallelogram with sloping sides.

FIG. 7 is a partial top view of a transparent multi point touch screen 120, in accordance with one embodiment of the present invention. In this embodiment, the touch screen 120 is similar to the touch screen 100 shown in FIG. 6, however, unlike the touch screen 100 of FIG. 6, the touch screen 120 shown in FIG. 7 includes electrodes 122 with different sizes. As shown, the electrodes 122 located in the center of the touch screen 120 are larger than the electrodes 122 located at the sides of the touch screen 120. In fact, the height of the electrodes 122 gets correspondingly smaller when moving from the center to the edge of the touch screen 120. This is done to make room for the sense traces 124 extending from the sides of the more centrally located electrodes 122. This arrangement advantageously reduces the gap found between adjacent rows 126 of electrodes 122. Although the height of each electrode 122 shrinks, the height H of the row 126 as well as the width W of each electrode 122 stays the same. In one configuration, the height of the row 126 is substantially equal to the width of each electrode 122. For example, the height of the row 126 and the width of each electrode 122 may be about 4 mm to about 5 mm.

FIG. 8 is a front elevation view, in cross section of a display arrangement 130, in accordance with one embodiment of the present invention. The display arrangement 130 includes an LCD display 132 and a touch screen 134 positioned over the LCD display 132. The touch screen may for example correspond to the touch screen shown in FIG. 6 or 7. The LCD display 132 may correspond to any conventional LCD display known in the art. Although not shown, the LCD display 132 typically includes various layers including a fluorescent panel, polarizing filters, a layer of liquid crystal cells, a color filter and the like.

The touch screen 134 includes a transparent electrode layer 136 that is positioned over a glass member 138. The glass member 138 may be a portion of the LCD display 132 or it may be a portion of the touch screen 134. In either case, the glass member 138 is a relatively thick piece of clear glass that protects the display 132 from forces, which are exerted on the touch screen 134. The thickness of the glass member 138 may for example be about 2 mm. In most cases, the electrode layer 136 is disposed on the glass member 138 using suitable transparent conductive materials and patterning techniques such as ITO and printing. Although not shown, in some cases, it may be necessary to coat the electrode layer 136 with a material of similar refractive index to improve the visual appearance of the touch screen. As should be appreciated, the gaps located between electrodes and traces do not have the same optical index as the electrodes and traces, and therefore a material may be needed to provide a more similar optical index. By way of example, index matching gels may be used.

The touch screen 134 also includes a protective cover sheet 140 disposed over the electrode layer 136. The electrode layer 136 is therefore sandwiched between the glass member 138 and the protective cover sheet 140. The protective sheet 140 serves to protect the under layers and provide a surface for allowing an object to slide thereon. The protective sheet 140 also provides an insulating layer between the object and the electrode layer 136. The protective cover sheet 140 may be formed from any suitable clear material such as glass and plastic. The protective cover sheet 140 is suitably thin to allow for sufficient electrode coupling. By way of example, the thickness of the cover sheet 140 may be between about 0.3-0.8 mm. In addition, the protective cover sheet 140 may be treated with coatings to reduce stiction when touching and reduce glare when viewing the underlying LCD display 132.

By way of example, a low stiction/anti reflective coating 142 may be applied over the cover sheet 140. Although the electrode layer 136 is typically patterned on the glass member 138, it should be noted that in some cases it may be alternatively or additionally patterned on the protective cover sheet 140.

FIG. 9 is a top view of a transparent multipoint touch screen 150, in accordance with another embodiment of the present invention. By way of example, the touch screen 150 may generally correspond to the touch screen of FIGS. 2 and 4. Unlike the touch screen shown in FIGS. 6-8, the touch screen of FIG. 9 utilizes the concept of mutual capacitance rather than self capacitance. As shown, the touch screen 150 includes a two layer grid of spatially separated lines or wires 152. In most cases, the lines 152 on each layer are parallel one another. Furthermore, although in different planes, the lines 152 on the different layers are configured to intersect or cross in order to produce capacitive sensing nodes 154, which each represent different coordinates in the plane of the touch screen 150. The nodes 154 are configured to receive capacitive input from an object touching the touch screen 150 in the vicinity of the node 154. When an object is proximate the node 154, the object steals charge thereby affecting the capacitance at the node 154.

To elaborate, the lines 152 on different layers serve two different functions. One set of lines 152A drives a current therethrough while the second set of lines 152B senses the capacitance coupling at each of the nodes 154. In most cases, the top layer provides the driving lines 152A while the bottom layer provides the sensing lines 152B. The driving lines 152A are connected to a voltage source (not shown) that separately drives the current through each of the driving lines 152A. That is, the stimulus is only happening over one line while all the other lines are grounded. They may be driven similarly to a raster scan. The sensing lines 152B are connected to a capacitive sensing circuit (not shown) that continuously senses all of the sensing lines 152B (always sensing).

When driven, the charge on the driving line 152A capacitively couples to the intersecting sensing lines 152B through the nodes 154 and the capacitive sensing circuit senses all of the sensing lines 152B in parallel. Thereafter, the next driving line 152A is driven, and the charge on the next driving line 152A capacitively couples to the intersecting sensing lines 152B through the nodes 154 and the capacitive sensing circuit senses all of the sensing lines 152B in parallel. This happens sequential until all the lines 152A have been driven. Once all the lines 152A have been driven, the sequence starts over (continuously repeats). In most cases, the lines 152A are sequentially driven from one side to the opposite side.

The capacitive sensing circuit typically includes one or more sensor ICs that measure the capacitance in each of the sensing lines 152B and that reports its findings to a host controller. The sensor ICs may for example convert the analog capacitive signals to digital data and thereafter transmit the digital data over a serial bus to a host controller. Any number of sensor ICs may be used. For example, a sensor IC may be used for all lines, or multiple sensor ICs may be used for a single or group of lines. In most cases, the sensor ICs 110 report tracking signals, which are a function of both the position of the node 154 and the intensity of the capacitance at the node 154.

The lines 152 are generally disposed on one or more optical transmissive members 156 formed from a clear material such as glass or plastic. By way of example, the lines 152 may be placed on opposing sides of the same member 156 or they may be placed on different members 156. The lines 152 may be placed on the member 156 using any suitable patterning

technique including for example, deposition, etching, printing and the like. Furthermore, the lines 152 can be made from any suitable transparent conductive material. By way of example, the lines may be formed from indium tin oxide (ITO). The driving lines 152A are typically coupled to the voltage source through a flex circuit 158A, and the sensing lines 152B are typically coupled to the sensing circuit, and more particularly the sensor ICs through a flex circuit 158B. The sensor ICs may be attached to a printed circuit board (PCB). Alternatively, the sensor ICs may be placed directly on the member 156 thereby eliminating the flex circuit 158B.

The distribution of the lines 152 may be widely varied. For example, the lines 152 may be positioned almost anywhere in the plane of the touch screen 150. The lines 152 may be positioned randomly or in a particular pattern about the touch screen 150. With regards to the later, the position of the lines 152 may depend on the coordinate system used. For example, the lines 152 may be placed in rows and columns for Cartesian coordinates or concentrically and radially for polar coordinates. When using rows and columns, the rows and columns may be placed at various angles relative to one another. For example, they may be vertical, horizontal or diagonal.

Furthermore, the lines 152 may be formed from almost any shape whether rectilinear or curvilinear. The lines on each layer may be the same or different. For example, the lines may alternate between rectilinear and curvilinear. Further still, the shape of the opposing lines may have identical shapes or they may have different shapes. For example, the driving lines may have a first shape while the sensing lines may have a second shape that is different than the first shape. The geometry of the lines 152 (e.g., linewidths and spacing) may also be widely varied. The geometry of the lines within each layer may be identical or different, and further, the geometry of the lines for both layers may be identical or different. By way of example, the linewidths of the sensing lines 152B to driving lines 152A may have a ratio of about 2:1.

Moreover, any number of lines 152 may be used. It is generally believed that the number of lines is dependent on the desired resolution of the touch screen 150. The number of lines within each layer may be identical or different. The number of lines is typically determined by the size of the touch screen as well as the desired pitch and linewidths of the lines 152.

In the illustrated embodiment, the driving lines 152A are positioned in rows and the sensing lines 152B are positioned in columns that are perpendicular to the rows. The rows extend horizontally to the sides of the touch screen 150 and the columns extend vertically to the top and bottom of the touch screen 150. Furthermore, the linewidths for the set of lines 152A and 152B are different and the pitch for set of lines 152A and 152B are equal to one another. In most cases, the linewidths of the sensing lines 152B are larger than the linewidths of the driving lines 152A. By way of example, the pitch of the driving and sensing lines 152 may be about 5 mm, the linewidths of the driving lines 152A may be about 1.05 mm and the linewidths of the sensing lines 152B may be about 2.10 mm. Moreover, the number of lines 152 in each layer is different. For example, there may be about 38 driving lines and about 50 sensing lines.

As mentioned above, the lines in order to form semi-transparent conductors on glass, film or plastic, may be patterned with an ITO material. This is generally accomplished by depositing an ITO layer over the substrate surface, and then by etching away portions of the ITO layer in order to form the lines. As should be appreciated, the areas with ITO tend to have lower transparency than the areas without ITO. This is generally less desirable for the user as the user can distinguish

the lines from the spaces therebetween, i.e., the patterned ITO can become quite visible thereby producing a touch screen with undesirable optical properties. To further exacerbate this problem, the ITO material is typically applied in a manner that produces a relatively low resistance, and unfortunately low resistance ITO tends to be less transparent than high resistance ITO.

In order to prevent the aforementioned problem, the dead areas between the ITO may be filled with indexing matching materials. In another embodiment, rather than simply etching away all of the ITO, the dead areas (the uncovered spaces) may be subdivided into unconnected electrically floating ITO pads, i.e., the dead areas may be patterned with spatially separated pads. The pads are typically separated with a minimum trace width. Furthermore, the pads are typically made small to reduce their impact on the capacitive measurements. This technique attempts to minimize the appearance of the ITO by creating a uniform optical retarder. That is, by seeking to create a uniform sheet of ITO, it is believed that the panel will function closer to a uniform optical retarder and therefore non-uniformities in the visual appearance will be minimized. In yet another embodiment, a combination of index matching materials and unconnected floating pads may be used.

FIG. 10 is a partial front elevation view, in cross section of a display arrangement 170, in accordance with one embodiment of the present invention. The display arrangement 170 includes an LCD display 172 and a touch screen 174 positioned over the LCD display 170. The touch screen may for example correspond to the touch screen shown in FIG. 9. The LCD display 172 may correspond to any conventional LCD display known in the art. Although not shown, the LCD display 172 typically includes various layers including a fluorescent panel, polarizing filters, a layer of liquid crystal cells, a color filter and the like.

The touch screen 174 includes a transparent sensing layer 176 that is positioned over a first glass member 178. The sensing layer 176 includes a plurality of sensor lines 177 positioned in columns (extend in and out of the page). The first glass member 178 may be a portion of the LCD display 172 or it may be a portion of the touch screen 174. For example, it may be the front glass of the LCD display 172 or it may be the bottom glass of the touch screen 174. The sensor layer 176 is typically disposed on the glass member 178 using suitable transparent conductive materials and patterning techniques. In some cases, it may be necessary to coat the sensor layer 176 with material of similar refractive index to improve the visual appearance, i.e., make more uniform.

The touch screen 174 also includes a transparent driving layer 180 that is positioned over a second glass member 182. The second glass member 182 is positioned over the first glass member 178. The sensing layer 176 is therefore sandwiched between the first and second glass members 178 and 182. The second glass member 182 provides an insulating layer between the driving and sensing layers 176 and 180. The driving layer 180 includes a plurality of driving lines 181 positioned in rows (extend to the right and left of the page). The driving lines 181 are configured to intersect or cross the sensing lines 177 positioned in columns in order to form a plurality of capacitive coupling nodes 182. Like the sensing layer 176, the driving layer 180 is disposed on the glass member using suitable materials and patterning techniques. Furthermore, in some cases, it may be necessary to coat the driving layer 180 with material of similar refractive index to improve the visual appearance. Although the sensing layer is typically patterned on the first glass member, it should be noted that in some cases it may be alternatively or additionally patterned on the second glass member.

The touch screen 174 also includes a protective cover sheet 190 disposed over the driving layer 180. The driving layer 180 is therefore sandwiched between the second glass member 182 and the protective cover sheet 190. The protective cover sheet 190 serves to protect the under layers and provide a surface for allowing an object to slide thereon. The protective cover sheet 190 also provides an insulating layer between the object and the driving layer 180. The protective cover sheet is suitably thin to allow for sufficient coupling. The protective cover sheet 190 may be formed from any suitable clear material such as glass and plastic. In addition, the protective cover sheet 190 may be treated with coatings to reduce stiction when touching and reduce glare when viewing the underlying LCD display 172. By way of example, a low stiction/anti reflective coating may be applied over the cover sheet 190. Although the line layer is typically patterned on a glass member, it should be noted that in some cases it may be alternatively or additionally patterned on the protective cover sheet.

The touch screen 174 also includes various bonding layers 192. The bonding layers 192 bond the glass members 178 and 182 as well as the protective cover sheet 190 together to form the laminated structure and to provide rigidity and stiffness to the laminated structure. In essence, the bonding layers 192 help to produce a monolithic sheet that is stronger than each of the individual layers taken alone. In most cases, the first and second glass members 178 and 182 as well as the second glass member and the protective sheet 182 and 190 are laminated together using a bonding agent such as glue. The compliant nature of the glue may be used to absorb geometric variations so as to form a singular composite structure with an overall geometry that is desirable. In some cases, the bonding agent includes an index matching material to improve the visual appearance of the touch screen 170.

With regards to configuration, each of the various layers may be formed with various sizes, shapes, and the like. For example, each of the layers may have the same thickness or a different thickness than the other layers in the structure. In the illustrated embodiment, the first glass member 178 has a thickness of about 1.1 mm, the second glass member 182 has a thickness of about 0.4 mm and the protective sheet has a thickness of about 0.55 mm. The thickness of the bonding layers 192 typically varies in order to produce a laminated structure with a desired height. Furthermore, each of the layers may be formed with various materials. By way of example, each particular type of layer may be formed from the same or different material. For example, any suitable glass or plastic material may be used for the glass members. In a similar manner, any suitable bonding agent may be used for the bonding layers 192.

FIGS. 11A and 11B are partial top view diagrams of a driving layer 200 and a sensing layer 202, in accordance with one embodiment. In this embodiment, each of the layers 200 and 202 includes dummy features 204 disposed between the driving lines 206 and the sensing lines 208. The dummy features 204 are configured to optically improve the visual appearance of the touch screen by more closely matching the optical index of the lines. While index matching materials may improve the visual appearance, it has been found that there still may exist some non-uniformities. The dummy features 204 provide the touch screen with a more uniform appearance. The dummy features 204 are electrically isolated and positioned in the gaps between each of the lines 206 and 208. Although they may be patterned separately, the dummy features 204 are typically patterned along with the lines 206 and 208. Furthermore, although they may be formed from different materials, the dummy features 204 are typically formed with the same transparent conductive material as the

lines as for example ITO to provide the best possible index matching. As should be appreciated, the dummy features will more than likely still produce some gaps, but these gaps are much smaller than the gaps found between the lines (many orders of magnitude smaller). These gaps, therefore have minimal impact on the visual appearance. While this may be the case, index matching materials may be additionally applied to the gaps between the dummy features to further improve the visual appearance of the touch screen. The distribution, size, number, dimension, and shape of the dummy features may be widely varied.

FIG. 12 is a simplified diagram of a mutual capacitance circuit 220, in accordance with one embodiment of the present invention. The mutual capacitance circuit 220 includes a driving line 222 and a sensing line 224 that are spatially separated thereby forming a capacitive coupling node 226. The driving line 222 is electrically coupled to a voltage source 228, and the sensing line 224 is electrically coupled to a capacitive sensing circuit 230. The driving line 222 is configured to carry a current to the capacitive coupling node 226, and the sensing line 224 is configured to carry a current to the capacitive sensing circuit 230. When no object is present, the capacitive coupling at the node 226 stays fairly constant. When an object 232 such as a finger is placed proximate the node 226, the capacitive coupling changes through the node 226 changes. The object 232 effectively shunts some of the field away so that the charge projected across the node 226 is less. The change in capacitive coupling changes the current that is carried by the sensing lines 224. The capacitive sensing circuit 230 notes the current change and the position of the node 226 where the current change occurred and reports this information in a raw or in some processed form to a host controller. The capacitive sensing circuit does this for each node 226 at about the same time (as viewed by a user) so as to provide multipoint sensing.

The sensing line 224 may contain a filter 236 for eliminating parasitic capacitance 237, which may for example be created by the large surface area of the row and column lines relative to the other lines and the system enclosure at ground potential. Generally speaking, the filter rejects stray capacitance effects so that a clean representation of the charge transferred across the node 226 is outputted (and not anything in addition to that). That is, the filter 236 produces an output that is not dependent on the parasitic capacitance, but rather on the capacitance at the node 226. As a result, a more accurate output is produced.

FIG. 13 is a diagram of an inverting amplifier 240, in accordance with one embodiment of the present invention. The inverting amplifier 240 may generally correspond to the filter 236 shown in FIG. 12. As shown, the inverting amplifier includes a non inverting input that is held at a constant voltage (in this case ground), an inverting input that is coupled to the node and an output that is coupled to the capacitive sensing circuit 230. The output is coupled back to the inverting input through a capacitor. During operation, the input from the node may be disturbed by stray capacitance effects, i.e., parasitic capacitance. If so, the inverting amplifier is configured to drive the input back to the same voltage that it had been previously before the stimulus. As such, the value of the parasitic capacitance doesn't matter.

FIG. 14 is a block diagram of a capacitive sensing circuit 260, in accordance with one embodiment of the present invention. The capacitive sensing circuit 260 may for example correspond to the capacitive sensing circuits described in the previous figures. The capacitive sensing circuit 260 is configured to receive input data from a plurality of

sensing points 262 (electrode, nodes, etc.), to process the data and to output processed data to a host controller.

The sensing circuit 260 includes a multiplexer 264 (MUX). The multiplexer 264 is a switch configured to perform time multiplexing. As shown, the MUX 264 includes a plurality of independent input channels 266 for receiving signals from each of the sensing points 262 at the same time. The MUX 264 stores all of the incoming signals at the same time, but sequentially releases them one at a time through an output channel 268.

The sensing circuit 260 also includes an analog to digital converter 270 (ADC) operatively coupled to the MUX 264 through the output channel 268. The ADC 270 is configured to digitize the incoming analog signals sequentially one at a time. That is, the ADC 270 converts each of the incoming analog signals into outgoing digital signals. The input to the ADC 270 generally corresponds to a voltage having a theoretically infinite number of values. The voltage varies according to the amount of capacitive coupling at each of the sensing points 262. The output to the ADC 270, on the other hand, has a defined number of states. The states generally have predictable exact voltages or currents.

The sensing circuit 260 also includes a digital signal processor 272 (DSP) operatively coupled to the ADC 270 through another channel 274. The DSP 272 is a programmable computer processing unit that works to clarify or standardize the digital signals via high speed mathematical processing. The DSP 274 is capable of differentiating between human made signals, which have order, and noise, which is inherently chaotic. In most cases, the DSP performs filtering and conversion algorithms using the raw data. By way of example, the DSP may filter noise events from the raw data, calculate the touch boundaries for each touch that occurs on the touch screen at the same time, and thereafter determine the coordinates for each touch event. The coordinates of the touch events may then be reported to a host controller where they can be compared to previous coordinates of the touch events to determine what action to perform in the host device.

FIG. 15 is a flow diagram 280, in accordance with one embodiment of the present invention. The method generally begins at block 282 where a plurality of sensing points are driven. For example, a voltage is applied to the electrodes in self capacitance touch screens or through driving lines in mutual capacitance touch screens. In the later, each driving line is driven separately. That is, the driving lines are driven one at a time thereby building up charge on all the intersecting sensing lines. Following block 282, the process flow proceeds to block 284 where the outputs (voltage) from all the sensing points are read. This block may include multiplexing and digitizing the outputs. For example, in mutual capacitance touch screens, all the sensing points on one row are multiplexed and digitized and this is repeated until all the rows have been sampled. Following block 284, the process flow proceeds to block 286 where an image or other form of data (signal or signals) of the touch screen plane at one moment in time can be produced and thereafter analyzed to determine where the objects are touching the touch screen. By way of example, the boundaries for each unique touch can be calculated, and thereafter the coordinates thereof can be found. Following block 286, the process flow proceeds to block 288 where the current image or signal is compared to a past image or signal in order to determine a change in pressure, location, direction, speed and acceleration for each object on the plane of the touch screen. This information can be subsequently used to perform an action as for example moving a pointer or cursor or making a selection as indicated in block 290.

FIG. 16 is a flow diagram of a digital signal processing method 300, in accordance with one embodiment of the present invention. By way of example, the method may generally correspond to block 286 shown and described in FIG. 15. The method 300 generally begins at block 302 where the raw data is received. The raw data is typically in a digitized form, and includes values for each node of the touch screen. The values may be between 0 and 256 where 0 equates to the highest capacitive coupling (no touch pressure) and 256 equates to the least capacitive coupling (full touch pressure). An example of raw data at one point in time is shown in FIG. 17A. As shown in FIG. 17A, the values for each point are provided in gray scale where points with the least capacitive coupling are shown in white and the points with the highest capacitive coupling are shown in black and the points found between the least and the highest capacitive coupling are shown in gray.

Following block 302, the process flow proceeds to block 304 where the raw data is filtered. As should be appreciated, the raw data typically includes some noise. The filtering process is configured to reduce the noise. By way of example, a noise algorithm may be run that removes points that aren't connected to other points. Single or unconnected points generally indicate noise while multiple connected points generally indicate one or more touch regions, which are regions of the touch screen that are touched by objects. An example of a filtered data is shown in FIG. 17B. As shown, the single scattered points have been removed thereby leaving several concentrated areas.

Following block 304, the process flow proceeds to block 306 where gradient data is generated. The gradient data indicates the topology of each group of connected points. The topology is typically based on the capacitive values for each point. Points with the lowest values are steep while points with the highest values are shallow. As should be appreciated, steep points indicate touch points that occurred with greater pressure while shallow points indicate touch points that occurred with lower pressure. An example of gradient data is shown in FIG. 17C.

Following block 306, the process flow proceeds to block 308 where the boundaries for touch regions are calculated based on the gradient data. In general, a determination is made as to which points are grouped together to form each touch region. An example of the touch regions is shown in FIG. 17D.

In one embodiment, the boundaries are determined using a watershed algorithm. Generally speaking, the algorithm performs image segmentation, which is the partitioning of an image into distinct regions as for example the touch regions of multiple objects in contact with the touchscreen. The concept of watershed initially comes from the area of geography and more particularly topography where a drop of water falling on a relief follows a descending path and eventually reaches a minimum, and where the watersheds are the divide lines of the domains of attracting drops of water. Herein, the watershed lines represent the location of pixels, which best separate different objects touching the touch screen. Watershed algorithms can be widely varied. In one particular implementation, the watershed algorithm includes forming paths from low points to a peak (based on the magnitude of each point), classifying the peak as an ID label for a particular touch region, associating each point (pixel) on the path with the peak. These steps are performed over the entire image map thus carving out the touch regions associated with each object in contact with the touchscreen.

Following block 308, the process flow proceeds to block 310 where the coordinates for each of the touch regions are

calculated. This may be accomplished by performing a centroid calculation with the raw data associated with each touch region. For example, once the touch regions are determined, the raw data associated therewith may be used to calculate the centroid of the touch region. The centroid may indicate the central coordinate of the touch region. By way of example, the X and Y centroids may be found using the following equations:

$$X_c = \sum x^2 / \sum Z; \text{ and}$$

$$Y_c = \sum y^2 / \sum Z,$$

where

X_c represents the x centroid of the touch region

Y_c represents the y centroid of the touch region

x represents the x coordinate of each pixel or point in the touch region

y represents the y coordinate of each pixel or point in the touch region

Z represents the magnitude (capacitance value) at each pixel or point

An example of a centroid calculation for the touch regions is shown in FIG. 17E. As shown, each touch region represents a distinct x and y coordinate. These coordinates may be used to perform multipoint tracking as indicated in block 312. For example, the coordinates for each of the touch regions may be compared with previous coordinates of the touch regions to determine positioning changes of the objects touching the touch screen or whether or not touching objects have been added or subtracted or whether a particular object is being tapped.

FIGS. 18 and 19 are side elevation views of an electronic device 350, in accordance with multiple embodiments of the present invention. The electronic device 350 includes an LCD display 352 and a transparent touch screen 354 positioned over the LCD display 352. The touch screen 354 includes a protective sheet 356, one or more sensing layers 358, and a bottom glass member 360. In this embodiment, the bottom glass member 360 is the front glass of the LCD display 352. Further, the sensing layers 358 may be configured for either self or mutual capacitance as described above. The sensing layers 358 generally include a plurality of interconnects at the edge of the touch screen for coupling the sensing layer 358 to a sensing circuit (not shown). By way of example, the sensing layer 358 may be electrically coupled to the sensing circuit through one or more flex circuits 362, which are attached to the sides of the touch screen 354.

As shown, the LCD display 352 and touch screen 354 are disposed within a housing 364. The housing 364 serves to cover and support these components in their assembled position within the electronic device 350. The housing 364 provides a space for placing the LCD display 352 and touch screen 354 as well as an opening 366 so that the display screen can be seen through the housing 364. In one embodiment, as shown in FIG. 18, the housing 364 includes a facade 370 for covering the sides the LCD display 352 and touch screen 354. Although not shown in great detail, the facade 370 is positioned around the entire perimeter of the LCD display 352 and touch screen 354. The facade 370 serves to hide the interconnects leaving only the active area of the LCD display 352 and touch screen 354 in view.

In another embodiment, as shown in FIG. 19, the housing 364 does not include a facade 370, but rather a mask 372 that is printed on interior portion of the top glass 374 of the touch screen 354 that extends between the sides of the housing 364. This particular arrangement makes the mask 372 look submerged in the top glass 356. The mask 372 serves the same

function as the facade 370, but is a more elegant solution. In one implementation, the mask 372 is formed from high temperature black polymer. In the illustrated embodiment of FIG. 19, the touch screen 354 is based on mutual capacitance sensing and thus the sensing layer 358 includes driving lines 376 and sensing lines 378. The driving lines 376 are disposed on the top glass 356 and the mask 372, and the sensing lines 378 are disposed on the bottom glass 360. The driving lines and sensing lines 376 and 378 are insulated from one another via a spacer 380. The spacer 380 may for example be a clear piece of plastic with optical matching materials retained therein or applied thereto.

In one embodiment and referring to both FIGS. 18 and 19, the electronic device 350 corresponds to a tablet computer. In this embodiment, the housing 364 also encloses various integrated circuit chips and other circuitry 382 that provide computing operations for the tablet computer. By way of example, the integrated circuit chips and other circuitry may include a microprocessor, motherboard, Read-Only Memory (ROM), Random-Access Memory (RAM), a hard drive, a disk drive, a battery, and various input/output support devices.

While this invention has been described in terms of several preferred embodiments, there are alterations, permutations, and equivalents, which fall within the scope of this invention. For example, although the touch screen was primarily directed at capacitive sensing, it should be noted that some or all of the features described herein may be applied to other sensing methodologies. It should also be noted that there are many alternative ways of implementing the methods and apparatuses of the present invention. It is therefore intended that the following appended claims be interpreted as including all such alterations, permutations, and equivalents as fall within the true spirit and scope of the present invention.

What is claimed is:

1. A touch panel comprising a transparent capacitive sensing medium configured to detect multiple touches or near touches that occur at a same time and at distinct locations in a plane of the touch panel and to produce distinct signals representative of a location of the touches on the plane of the touch panel for each of the multiple touches, wherein the transparent capacitive sensing medium comprises:
 - a first layer having a plurality of transparent first conductive lines that are electrically isolated from one another; and
 - a second layer spatially separated from the first layer and having a plurality of transparent second conductive lines that are electrically isolated from one another, the second conductive lines being positioned transverse to the first conductive lines, the intersection of transverse lines being positioned at different locations in the plane of the touch panel, each of the second conductive lines being operatively coupled to capacitive monitoring circuitry; wherein the capacitive monitoring circuitry is configured to detect changes in charge coupling between the first conductive lines and the second conductive lines.
2. The touch panel as recited in claim 1 wherein the conductive lines on each of the layers are substantially parallel to one another.
3. The touch panel as recited in claim 2 wherein the conductive lines on different layers are substantially perpendicular to one another.

4. The touch panel as recited in claim 1 wherein the transparent first conductive lines of the first layer are disposed on a first glass member, and wherein the transparent second conductive lines of the second layer are disposed on a second glass member, the first glass member being disposed over the second glass member.

5. The touch panel as recited in claim 4 further including a third glass member disposed over the first glass member, the first and second glass members being attached to one another via an adhesive layer, the third glass member being attached to the first glass member via another adhesive layer.

6. The touch panel as recited in claim 1 wherein the conductive lines are formed from indium tin oxide (ITO).

7. The touch panel as recited in claim 1, wherein the capacitive sensing medium is a mutual capacitance sensing medium.

8. The touch panel as recited in claim 7, further comprising a virtual ground charge amplifier coupled to the touch panel for detecting the touches on the touch panel.

9. The touch panel as recited in claim 1, the transparent capacitive sensing medium formed on both sides of a single substrate.

10. A display arrangement comprising:
a display having a screen for displaying a graphical user interface; and

a transparent touch panel allowing the screen to be viewed therethrough and capable of recognizing multiple touch events that occur at different locations on the touch panel at a same time and to output this information to a host device to form a pixilated image;

wherein the touch panel includes a multipoint sensing arrangement configured to simultaneously detect and monitor the touch events and a change in capacitive coupling associated with those touch events at distinct points across the touch panel; and

wherein the touch panel comprises:
a first glass member disposed over the screen of the display;

a first transparent conductive layer disposed over the first glass member, the first transparent conductive layer comprising a plurality of spaced apart parallel lines having the same pitch and linewidths;

a second glass member disposed over the first transparent conductive layer;

a second transparent conductive layer disposed over the second glass member, the second transparent conductive layer comprising a plurality of spaced apart parallel lines having the same pitch and linewidths, the parallel lines of the second transparent conductive layer being substantially perpendicular to the parallel lines of the first transparent conductive layer;

a third glass member disposed over the second transparent conductive layer; and

one or more sensor integrated circuits operatively coupled to the lines.

11. The display arrangement as recited in claim 10 further including dummy features disposed in the space between the parallel lines, the dummy features optically improving the visual appearance of the touch screen by more closely matching the optical index of the lines.
