**1. Record of Decision -- Selected Pages**

### **Human Health Risk Assessment Methodology**

The environmental sampling data were collected in accordance with knowledge-based, purposive sampling decision logic, with additional samples to provide data in areas of high, medium, and low contamination. All RI data were validated and evaluated in accordance with the EPA's *Risk Assessment Guidance for Superfund (RAGS)* (EPA, 1989b).

Exposure scenarios were developed based on available media at the site and current and future land use. The reasonable maximum exposure (RME) receptor was assumed to be present on site for all exposure scenarios.

Toxicity values for the chemicals of concern (COCs) were compiled from the *Integrated Risk Information System (IRIS)* (EPA, 1992a), *Health Effects Assessment Summary Tables (HEAST)* (EPA, 1992b), a Cal/EPA memorandum on criteria for carcinogens (Cal/EPA, 1992a), and tetrachloroethene (PCE) and TCE profiles from the Superfund Health Risk Technical Support Center (EPA, 1994). For the more recent risk assessments conducted after the EPA PRG tables (EPA, 1995 and 1996a) were developed, toxicity values were cited from the above sources, as well as from the National Center for Environmental Assessment.

Cancer slope factors (SFs) have been developed by the EPA for estimating excess lifetime cancer risks associated with exposure to potentially carcinogenic chemicals. SF values, expressed in milligrams per kilogram per day (mg/kg-day)<sup>-1</sup>, are multiplied by the estimated intake of a potential carcinogen (expressed in mg/kg-day) to provide an upper-bound estimate of the excess lifetime cancer risk associated with exposure at that intake level. The term "upper bound" reflects the conservative estimate of the risks calculated from the SF. This approach makes underestimation of the actual cancer risk highly unlikely. Cancer SF values are derived from the results of human epidemiological studies or chronic animal bioassays using animal-to-human extrapolation and uncertainty factors.

Reference doses (RfDs) have been developed by the EPA to indicate the potential for adverse health effects from exposure to chemicals exhibiting noncarcinogenic effects. RfDs (expressed in mg/kg-day) are estimates of lifetime daily exposure levels for humans, including sensitive individuals. Estimated intakes of chemicals from environmental media (e.g., the amount of a chemical ingested from contaminated drinking water) can be compared with the RfD. RfDs are derived from human epidemiological studies or animal studies and incorporate uncertainty factors

(e.g., to account for the use of animal data to predict effects on humans). These uncertainty factors help ensure that the RfDs will not underestimate the potential for adverse effects.

Excess lifetime cancer risks are determined by multiplying the intake level with the cancer SF value. These risks are probabilities that are generally expressed in scientific notation (e.g.,  $1 \times 10^{-6}$ ). An excess lifetime cancer risk of  $1 \times 10^{-6}$  indicates that, as a plausible upper bound, an individual has a one in one million chance of developing cancer as a result of site-related exposure to a carcinogen over a 70-year lifetime under the specific exposure conditions at a site.

Potential concern for noncarcinogenic effects of a single contaminant in a single medium is expressed as the hazard quotient (HQ) (or the ratio of the estimated intake derived from the contaminant concentration in a given medium to the RfD for the contaminant). The hazard index (HI) can be derived by adding the HQs for all contaminants within a medium or across all media to which a given population could reasonably be exposed. The HI provides a useful reference point for gaging the potential significance of multiple contaminant exposures within a single medium or across media.

Lead was evaluated separately using both the Federal (EPA, 1991) and State (Cal/EPA, 1992b) lead models. Evaluation of soil and groundwater lead concentrations using Federal and State blood lead models indicated that blood lead concentrations would meet health protection target criteria. The target criteria are less than 10 micrograms per deciliter (mg/dl) for 95 percent of children (age range 0 to 6 years) using the Federal model and for 99 percent of children using the State model.

The EPA has developed a list of media-specific concentrations (PRGs) that represent a  $1 \times 10^{-6}$  risk level (EPA, 1995 and 1996a). Soil and groundwater pathways were evaluated using the methodology described above to calculate excess lifetime cancer risk and noncarcinogenic effects. The target risk level of  $1 \times 10^{-6}$  and upper-bound intake parameters were used to calculate concentrations. Site concentrations were then compared against these concentrations to calculate risks and hazards.

The quantitative results of the baseline risk assessments were compared against target risk criteria. An RME excess lifetime cancer risk of  $10^{-6}$  is considered the point of departure above which risk management should be considered, according to Title 40, Code of Federal Regulations (CFR),

Section 300.430(e)(2)(i)(A)(2). An excess lifetime cancer risk exceeding  $10^{-4}$  generally requires remediation. Risk management should also be considered for an RME exposure with an HI greater than 1.0.

Risks/hazards associated with chemicals of potential concern (COPCs) were evaluated using maximum and representative (95 percent upper confidence limit [UCL]) concentrations for residential land use and commercial industrial exposure scenarios.

### **Ecological Risk Assessment Methodology**

The baseline ecological risk assessment (EcoRA) methodology is presented in detail in the RI reports and work plans for the sites included in this ROD (SWDIV, 1991, 1993a, 1993b, 1995b, 1996a, and 1998). This section summarizes the approach and methodology for the baseline EcoRA.

To address the EcoRA objectives, a phased approach is used, as suggested by the EPA (1992c). This approach consists of three phases: site characterization and screening, initial determination of ecological impact, and bioassessment.

- **Phase I - Site Characterization and Screening**, involves identifying the presence and concentrations of chemicals of potential ecological concern (COPECs) at the sites and evaluating whether exposure pathways to ecological receptors exist.
- **Phase II - Initial Determination of Ecological Impact**, involves conducting ecological comparisons between potentially impacted and nonimpacted areas. The comparison can include parameters such as the presence or absence of species, health of plants and animals, community structure, and contaminant concentrations in the tissues of plants and animals in order to assess potential food-chain exposure. This phase includes habitat and wildlife surveys and collection of biota to measure bioaccumulation in plants, terrestrial invertebrates, and small mammals.
- **Phase III - Bioassessment**, involves further laboratory studies to determine what COPEC concentrations result in measurable effects. Information collected as part of this phase is used to help make decisions about potential remediation.

Quantification of potential risks to representative species was conducted using an HQ approach. An HQ was calculated for each preliminary COPEC (soil and biota) or sample location (sediment and surface water). The HQ was calculated by dividing the maximum detected concentration by

### **Human Health Risk Characterization**

The probable sources of contamination at Site 1A are the refuse burning ground, surface soils, and subsurface soils. Potential transport and/or retention medium are surface-water runoff, air, and surface and subsurface soils. The potential receptors are residents or site workers, and the primary exposure points are air and surface/subsurface soils. A secondary exposure point for potential future residents is groundwater. Because only the residential land use scenario was used to determine whether a site was recommended for further action, this is the only land use scenario discussed in this section.

Analytical results from the Group D RI (SWDIV, 1997b) were used as a basis for the HHRA. The HHRA was conducted using only the results from the Phase 1 investigation because additional soil samples for Phase 2 were collected from Phase 1 locations and the results were similar.

The risk screening for soil exposure using maximum concentrations of COPCs results in a cumulative residential risk of  $1.4 \times 10^{-4}$  and is primarily attributable to arsenic. Excluding that portion of the risk attributable to naturally occurring metals, the EPA Region IX and Cal/EPA incremental lifetime cancer risk (ILCR) values are  $9.7 \times 10^{-5}$  and  $9.9 \times 10^{-5}$ , respectively. Both values are within the risk management range.

Replacing the maximum concentrations with the 95 percent UCL concentrations of the COPCs and excluding the portion of the risk attributable to naturally occurring metals results in EPA Region IX and Cal/EPA ILCRs of  $9.1 \times 10^{-5}$  and  $9.2 \times 10^{-5}$ , respectively. These values are also within the risk management range.

The cumulative residential HI for maximum detected COPCs is 19.0. Using the representative concentrations, the cumulative residential HI is 14.0. Background metals contribute an incremental hazard of 1.7. The primary contributors to the HI are arsenic, copper, and thallium, each of which has an individual HI exceeding 1.0. The maximum lead concentration is 8,800 mg/kg. This exceeds the background concentration for the San Luis Rey Basin (10.2 mg/kg) and is at least one order of magnitude greater than the EPA residential soil PRG of 400 mg/kg and the Cal/EPA residential soil PRG of 130 mg/kg.

As presented in the Group D RI report (SWDIV, 1997b), Site 1A soil represents an acceptable cancer risk under the residential exposure but may present an unacceptable noncarcinogenic

hazard; the HI exceeds the threshold value of 1.0. Final human health COCs for soils are arsenic, copper, thallium, and lead. \*

Excess cancer risk and noncarcinogenic health hazard for the future residential exposure scenario were evaluated for the groundwater pathway. No cancer risk was estimated because no carcinogenic contaminants were detected in groundwater. The HI is 1.6 and is primarily attributable to manganese (approximately 81 percent of the total hazard). For individual target organs, only the central nervous system exceeds the noncarcinogenic hazard criterion of 1.0 (HQ 1.3).

Uncertainty in the RfD used to calculate the PRG for manganese could result in an overestimation of hazard. In addition, uncertainty is associated with the results for the groundwater sample, which was collected from a temporary well. Temporary well groundwater samples usually have higher TSS (the sample is usually muddy) than samples from permanent wells because of the disturbance associated with the sampling method. Because samples from temporary wells contain more particles, more nondissolved particles could pass through the filter used in the field (Hem, 1985) and could result in a higher concentration of manganese in temporary well samples. Manganese is also naturally occurring, and some of the manganese in groundwater at Site 1A is assumed to be within the background concentration.

Groundwater at Site 1A is considered protective of human health for the following reasons:

- No carcinogenic chemicals were detected in groundwater.
- The HI only slightly exceeds 1.0 (HQ 1.3) for one target organ, the central nervous system, and the uncertainty associated with toxicity of manganese could result in an overestimation of hazard.
- A portion of the manganese concentration is likely background rather than site related.

#### **Summed Groundwater and Soil Human Health Risk and Hazard**

If it is conservatively assumed that under the future unrestricted residential use scenario a hypothetical resident could be exposed to soil contaminants and groundwater through domestic use, the incremental site risks and hazards for soil and groundwater can be summed for an overall residential exposure. Because no carcinogenic COCs were detected in groundwater at Site 1A,

The results of the EcoRA indicate that antimony, copper, iron, lead, and zinc are present in Site 1D soils at concentrations that could be directly toxic to ecological receptors or could bioaccumulate in the wildlife food chain.

#### **2.4.1.4.3 Site 1E - Refuse Burning Ground in 32 Area**

This section summarizes the results of the HHRA and EcoRA for Site 1E.

##### **Human Health Risk Characterization**

The conceptual site model for Site 1E indicates that current/future workers and potential future residents could be exposed to soil contaminants through incidental ingestion, dermal contact, and inhalation of VOCs and soil particulates. There are no complete groundwater exposure pathways at this site. The primary source of contaminants is burned and/or partially burned refuse; the secondary source is underlying or adjacent soils. Analytical results collected during the Group C RI (SWDIV, 1996a) were used for the risk assessment.

The risk screening for soil exposure using maximum detected concentrations for residential land use results in a cumulative residential risk of  $6 \times 10^{-4}$  and an HI of 20.1. Subtracting the portion of risk and hazard contributed by background concentrations, the ILCR is  $4 \times 10^{-4}$  and the HI is 18.4. The site-related primary contributors to risk and/or hazard are antimony, arsenic, and chromium. In addition, the maximum lead concentration of 1,610 mg/kg exceeds background, the EPA residential PRG of 400 mg/kg, and the Cal/EPA residential soil PRG of 130 mg/kg.

The ILCR and the HI both exceed EPA acceptable levels, and evaluation of remedial actions was recommended.

##### **Ecological Risk Assessment**

Habitat at Site 1E consists primarily of California sagebrush series habitat. Various herpetiles, birds, and mammals were observed on site during general wildlife surveys. Pairs of coastal California gnatcatchers, a special-status species, were also observed at Site 1E. Representative species were selected for this site based on habitat types and include plants, terrestrial invertebrates, Pacific pocket mouse, California quail, and California gnatcatcher.

Concentrations of inorganic chemicals at Site 1E were compared with background values for the Santa Margarita Basin. Concentrations of 17 preliminary inorganic COPECs exceeded available

plants were the only representative species for which PLEs were exceeded, and the HQs are close to 1.0. Silver was detected at locations 1ESS002 and 1ESS003 only. At 1ESS002, the HQs for silver only slightly exceeded the plant PLE (HQ of 1.04). At 1ESS003, only one of the detected results exceeded the plant and invertebrate PLEs; the HQs for the other detected silver concentrations were less than 1.0.

The results of the EcoRA indicate that several inorganic chemicals are present in Site 1E soils at concentrations that could be directly toxic to ecological receptors or could bioaccumulate in the wildlife food chain.

#### **2.4.1.4.4 Site 1F - Refuse Burning Ground in 43 Area**

This section summarizes the results of the HHRA and EcoRA for Site 1F.

##### **Human Health Risk Characterization**

The conceptual site model for Site 1F indicates that current/future residents could be exposed to soil contaminants through incidental ingestion, dermal contact, and inhalation. The model also indicates that potential future residents could be exposed to groundwater contaminants through ingestion, inhalation of VOCs, and dermal contact. The primary source of contaminants is burned or partially burned refuse, and the secondary source is underlying or adjacent soils. Analytical results from samples collected during the Group D RI (SWDIV, 1997b) were used for the risk assessment.

The risk screening for soils using the maximum detected chemical concentrations results in a cumulative residential risk of  $3 \times 10^{-5}$ . Subtracting the portion of total risk attributable to naturally occurring metals or background, the ILCR is  $2.2 \times 10^{-6}$ . The cumulative residential HI for maximum detected contaminants is 8.7. Subtracting the portion attributable to background metals, the incremental HI is 7.5. The maximum lead concentration (1,260 mg/kg) exceeds the EPA residential soil screening value of 400 mg/kg and the Cal/EPA residential soil PRG of 130 mg/kg.

Because the HI exceeds the threshold criterion of 1.0, further risk evaluation for soil was conducted using a more reasonable value, the 95 percent UCL of the average concentration. Using the 95 percent UCL, the ILCRs for the residential scenario based on Region IX and Cal/EPA PRGs are  $9.9 \times 10^{-6}$  and  $1.2 \times 10^{-5}$ . The incremental HI is 7.3. The HI results primarily from a single high detection of copper at 12,500 mg/kg. This detection is a duplicate of the original sample,

which had a reported concentration of 821 mg/kg. As such, a degree of uncertainty is associated with the copper results. Lead and antimony are the other main contributors to hazard.

Potential residential carcinogenic risks for soil are within the risk management range and are considered acceptable for this site. However, potential noncarcinogenic hazard exceeds the acceptable criterion of 1.0, thus requiring further action.

To evaluate potential risks due to groundwater exposure, maximum concentrations were used for a residential scenario. The ILCR is  $5.2 \times 10^{-4}$  and is completely attributable to arsenic. However, the maximum reported value of arsenic, 23.4 micrograms per liter ( $\mu\text{g/l}$ ), is less than the MCL of 50  $\mu\text{g/l}$ . The noncarcinogenic HI is 3.9 and is primarily attributable to arsenic and boron. As stated, the maximum arsenic concentration is less than the MCL and would not likely represent a threat to human health via ingestion. Boron is not likely a result of site-related activities. For the above stated reasons, groundwater at Site 1F is considered protective of human health.

#### **Ecological Risk Assessment**

Two brushfires have disturbed the habitat at Site 1F. One fire occurred in June 1996, just prior to the initial site habitat evaluation. The second brushfire occurred in early summer 1997 between site visits to evaluate special-status species. Prior to the second fire, the site was sparsely vegetated with California sagebrush series habitat. Various birds, the black-tailed hare, house mice, and deer mice were observed at the site. No coastal California gnatcatchers or least Bell's vireos, both special-status species, were observed at the site prior to the 1997 brushfire. However, least Bell's vireos were identified in riparian vegetation along Pulgas Creek adjacent to the site. The representative species selected for evaluation of this site include plants, terrestrial invertebrates, Belding's savannah sparrow, and deer mouse.

Potential ecological risks at Site 1F were evaluated using the RI data and sampling locations presented in the draft final Group D RI report (SWDIV, 1997b).

Concentrations of inorganic chemicals detected at the site were compared with background values for the Las Flores Basin background area. Background values were available for all inorganic chemicals detected except boron. Concentrations of 14 preliminary inorganic COPBCs exceeded available background values and were retained for the initial ecological risk screening, along with boron and all detected preliminary organics. The results of the initial screening indicated that the

#### 2.4.2.3.1 Geology and Hydrogeology

Geologic data were derived from the five soil borings advanced at the site. Shallow geology at the site is characterized by semiconsolidated to consolidated alluvium consisting of fine-to medium-grained, poorly graded sand, silt, and sand with silt. The alluvium overlies massive granitic basement rock. Basement granitic rock was encountered in all five soil borings at depths ranging from 3.5 to 18 feet. Based on site geology, groundwater is assumed to flow to the southwest, following surface topography. Using groundwater elevations from a nearby site and ground surface elevations, the depth to groundwater at site 2A is estimated to be nearly 100 feet below grade. No perched surface water is present in the vicinity of Site 2A.

#### 2.4.2.3.2 Soil Results

The analytical results for soil are summarized in Figure 2-5. Only results that exceed background and PRGs or PLEs are shown.

##### Organics

Two chlorinated pesticides were detected at concentrations at or exceeding PRGs at Site 2A: 4,4'-DDD in the 5-foot interval sample and 4,4'-DDE in the 5- and 10-foot interval samples from boring 2AB-05. In addition, 15 other organic contaminants were detected at concentrations below PRGs. Four VOCs were detected at low concentrations: acetone, 2-butanone, ethylbenzene, and total xylenes. The highest VOC concentration detected at Site 2A was 0.047 mg/kg for acetone. The SVOCs benzoic acid (3.8 mg/kg), bis(2-ethylhexyl)phthalate (0.13 mg/kg), and phenanthrene (0.18 mg/kg) were each detected once in borings 2AB-03, 2AB-05, and 2AB-01, respectively. Eight dioxin/furans were detected in the 5- and 10-foot samples from boring 2AB-05 at concentrations of 0.001 mg/kg or less.

1,2,3,4,6,7,8-Heptachlorodibenzo-p-dioxin (1,2,3,4,6,7,8-HpCDD), 4,4'-DDE, 4,4'-DDT, and total heptachlorodibenzo-p-dioxins (total HpCDD) exceeded PLEs in soil samples collected from boring 2AB-05 during June 1996. The sampling conducted during May 1997 confirmed the presence of these pesticides.

##### Inorganics

A total of 9 metals were detected at concentrations exceeding PRGs: antimony, arsenic, beryllium, cadmium, copper, lead, manganese, thallium, and zinc. Although all arsenic detections exceeded the PRG, the concentrations were at or near background. All beryllium concentrations

were below the calculated background level. Antimony, cadmium, copper, lead, manganese, thallium, and zinc concentrations exceeded PRGs and background concentrations in samples from boring 2AB-05. In addition, the lead concentration for the 5-foot sample from boring 2AB-03 exceeded the PRG and background.

Concentrations of aluminum, antimony, barium, boron, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, silver, thallium, vanadium, and zinc exceeded PLEs in various boring locations. The maximum concentrations of these inorganic constituents also exceeded background concentrations. Boring location 2AB-05 had the greatest number of inorganic constituents with concentrations exceeding PLEs. The results for the surface samples collected near boring location 2AB-05 in 1997 are similar to the results for soil samples collected from the same location in June 1996.

#### **2.4.2.4 Summary of Risks Associated with Site 2A**

The HHRA was completed using data from the Phase 1 RI (SWDIV, 1997b). Because the samples for the Phase 2 RI (SWDIV, 1998a) were collected from the same locations as Phase 1 samples and the results were similar for both phases, the HHRA was not revised. The EcoRA was completed using both Phase 1 and Phase 2 results.

##### **2.4.2.4.1 Human Health Risk Characterization**

Based on the conceptual site model developed in the RI, current/future residents could be exposed to soil contaminants through incidental ingestion, dermal contact, and inhalation of VOCs and particulates. Groundwater was not considered a complete exposure pathway for current/future workers or residents. Data collected during the Group D RI were used for the risk assessment.

The cancer risk and noncarcinogenic hazard for the residential and industrial/commercial scenarios were evaluated using maximum detected contaminant concentrations in soils. Only the residential scenario is summarized here because decisions for the site were based on this scenario. The cumulative residential risk is  $5 \times 10^{-5}$  and is attributable primarily to arsenic. Subtracting the portion of total risk attributable to background metals, the ILCRs based on Region IX and Cal/EPA PRGs are  $5.6 \times 10^{-6}$  and  $1.2 \times 10^{-5}$ , respectively. The cumulative residential HI is 150. The primary hazard contributors are manganese, thallium, and zinc. Manganese and zinc concentrations exceed background concentrations by more than three orders of magnitude.

The highest detections of contaminants, driving both the cancer risk and the noncancer hazard, were found at boring location 2AB-05, which is located in the adjacent burn area. Therefore, the site was viewed as two separate areas, the grease disposal pit area and the burn area, and the risks were reassessed.

The maximum concentrations for the grease disposal pit, excluding the samples from the burn area at boring 2AB-05, were compared against EPA Region IX soil PRGs. The results were a cumulative ILCR of  $9.8 \times 10^{-4}$  and an HI of 1.8. The only contributors are arsenic and beryllium, both of which are within the range of background concentrations. Subtracting the contribution from background, the ILCR for the residential scenario using EPA Region IX and Cal/EPA PRGs are less than  $1 \times 10^{-4}$  and  $1 \times 10^{-4}$ , respectively. The HI is 1.0. Based on this assessment, soil in the grease disposal pit area is considered protective of human health. However, the area surrounding boring 2AB-05 appears to present both an unacceptable carcinogenic risk and noncarcinogenic hazard. The human health COCs in this area are 4,4'-DDD, 4,4'-DDE, antimony, arsenic, cadmium, copper, lead, manganese, thallium, and zinc.

#### 2.4.2.4.2 Ecological Risk Assessment

Vegetation at Site 2A burned during a brushfire in June 1997. Most of the existing California sagebrush series habitat and disturbed habitat were destroyed. Bird species observed prior to the fire included cliff swallow, California quail, California towhee, and song sparrow. Mammals observed included black-tail hare, cactus mouse, California mouse, deer mouse, desert woodrat, dusky-footed woodrat, and house mouse. Surveys for the California gnatcatcher and the acroyo toad, both special-status species, were conducted in May 1997, but none were observed. Surveys conducted in 1996 identified least Bell's vireo, also a special-status species, in riparian vegetation adjacent to the site. The representative species selected for evaluation at this site based on habitat types present are plants, terrestrial invertebrates, California gnatcatcher, Belding's savannah sparrow, California mouse, and deer mouse.

Concentrations of inorganic chemicals detected at Site 2A were compared against background concentrations for the San Luis Rey Basin. Inorganic contaminants that exceeded background, boron, and all organic contaminants detected were retained for the initial ecological risk screening. Results of the initial ecological risk screening indicated that 18 inorganics, 2 organochlorine pesticides, and 2 dioxin analytes had HQs exceeding 1.0.
