ABSTRACT [57]

A power conservation system for use in a computer system. The power conservation system has an activity monitor and a plurality of modes of operation. The power conservation system has a power switching unit which couples the power supply to a selected group of the computer system circuits depending upon the power mode of operation. By controlling the power mode in response to the activity of the computer system, the power consumption of the computer system can be controlled.

MULTI-MODE POWER SWITCHING FOR COMPUTER SYSTEMS

CROSS REFERENCE RELATED U.S. PATENT APPLICATION

This is a continuation of application Ser. No. 08/459.341 filed 2 Jun. 1995 now abandoned which is a continuation of prior application Ser. No. 08/285,169, filed 3 Aug. 1994 now abandoned. which is a continuation of application Ser. No. 08/017.975, filed 12 Feb. 1993, now U.S. Pat. No. 5,396, 10 635, which is a continuation of application Ser. No. 07/908, 533, filed 29 Jun. 1992 now abandoned, which is a continuation of application Ser. No. 07/532,314, filed 1 Jun. 1990 now abandoned.

BACKGROUND OF THE INVENTION

A portion of the disclosure of this patent document contains material which is subject to copyright protection. The copyright owner has no objection to the facsimile reproduction by anyone of the patent document or the patent 20 disclosure, as it appears in the Patent and Trademark Office patent file or records, but otherwise reserves all copyright rights whatsoever.

The present invention relates to computers and particularly to methods and apparatus for power management in ²⁵ computers, particularly in battery-powered computers.

The major parts of computers include a central processing unit (CPU), input/output (I/O) devices such as display screens, keyboards, modems, printers, disk drives and the like, and storage (memory).

The CPU communicates with the I/O devices, with the storage and otherwise operates with addresses defined within the computer address range. Typically, addresses for I/O devices are within an I/O address range. Addresses for $_{35}$ execution of programs without I/O reference typically are within a memory address range. Similarly, that portion of memory allocated for display is within a video memory address range.

Computers function to execute application programs such 40 as word processing, spreadsheet and data base management programs. Typically, the computer and the application programs are under the control of a software operating system that manages the different system parts and resources including some I/O devices. For example, during the execution of 45 an application program when the CPU wishes to check to determine if any key has been depressed on the keyboard, the CPU through a subroutine call to the operating system requests the operating system through execution of a subroutine to perform a key-actuation detection task. Since the $_{50}$ operating system performs many such tasks, the operating system has a detailed knowledge of many activities within the computer. However, under some circumstances, application programs bypass the operating system and directly an I/O address within an I/O address range. For application programs which directly address I/O devices without operating system calls, the operating system is not immediately aware of I/O activity. With such complex operation in computers, the task of power conservation is difficult. 60

The need for power conservation is well known in battery-powered computers and must be performed in a manner that does not interfere with the operation of the computer or impede users from interacting with the computer during the execution of application programs.

Conservation of power has been utilized for some parts of battery-powered computers but has been ignored for other

parts of such computers. In general, power consumption is distributed in battery-powered computers among the major parts of those computers. One part with significant power consumption is the central processing unit (CPU). Another part is the input/output (I/O) devices such as display screens. keyboards, modems, printers, disk drives and the like. Still another part with significant power consumption is storage (memory).

Prior art attempts at conserving power have employed screen blanking which reduces the power to the display screen when the screen has not been used for some period of time. Typically, a timeout circuit senses changes in screen information and, if no change has occurred for a predetermined timeout period, the backlight to the screen is turned off for power reduction. While screen blanking is effective 15 in reducing power for the display screen, no reduction results in power to the driver circuitry for the display, to the CPU, or to other parts of the computer. Furthermore, when the screen is blanked, the computer cannot be used until reset.

Other prior art attempts at conserving power consumption have focused on disk drives because the power consumption of rotating magnetic disks is high. Disk drive manufacturers have employed various schemes for reducing the power consumption of the disk drive. While such power consumption schemes are effective for the disk drive, no reduction results in power to the CPU or other parts of the computer. Computers without disk drives, such as small "notebook" computers, have no need, of course, for the conservation of 30 power in a disk drive.

In order to extend the battery life of portable computers and to manage power in computers, there is a need for improved power management methods and apparatus in computers, particularly for power management that can be extended to many different parts and conditions of the computer.

SUMMARY OF THE INVENTION

The present invention is a method and apparatus for power management in a computer. The computer typically includes as hardware a central processing unit (CPU), storage (memory) and I/O devices and includes as software an operating system adapted to control the computer during application program execution.

The power management method and apparatus causes the computer system to enter the power conservation mode after sensing inactivity by a software monitor or by a hardware monitor.

The software monitor monitors the activity of the operating system or other software in the system. The software monitor typically is a software module linked, for example, to the operating system at boot time for monitoring subroutine calls to the operating system.

The hardware monitor monitors the hardware to detect address I/O devices. Typically, each I/O device is assigned 55 inactivity. The hardware monitor typically is circuitry for detecting inactivity independently from the software. For example, the hardware monitor senses predetermined address ranges, such as an I/O address range and a video memory address range, and monitors the activity of addresses by the CPU to addresses within these ranges. If no data transfers occur within the specified address ranges for predetermined periods of time, then a power conservation mode is entered to conserve power in the computer system.

> By using both a software monitor and a hardware monitor, 65 the power management unit determines exactly when to enter into power conservation mode without sacrificing system performance.

In the software monitor, inactivity is determined by detecting how many "active" or "idle" function calls an application makes within some time period. In the IBM PC DOS environment, the activity status is checked, for example, no less frequently than every 50 milliseconds. 5 There are 256 IBM PC DOS function calls and, in principle, each is labeled as "idle" or "active" and each is assigned a corresponding positive or negative number. A positive number is assigned to an "active" function call and a negative number to an "idle" function call.

The power management software monitor forms an activity measurement as a running total of the function call numbers as the function calls are made. Whenever a function call is made (either active or conservation), the power management software monitor algebraically adds the function call number to the accumulated value and determines whether the system is to remain in the active mode or be switched to the conservation mode by comparing the magnitude of the accumulated value with a function call threshold.

The function call threshold for determining activity is a variable depending on the computer system speed. To prevent the system from oscillating between the active and conservation mode due to minor changes in system activity, hysterisis is provided by using active and conservation ²⁵ function call thresholds. The accumulated total for the activity measurement is reset after it reaches the active threshold going in one direction or the conservation threshold going in the opposite direction as the case may be.

The active and conservation thresholds are typically ³⁰ unequal so that the entry and exit from conservation mode is biased. For example, in order to have the system enter the conservation mode quickly and thereby to reduce power consumption, the active threshold is set with a number greater than the number for the conservation threshold.

In one embodiment, functions that require immediate attention are assigned numbers large relative to the active and idle thresholds so that a single occurrence of the function call will force the accumulated count over the active threshold and thus force the system to be in the active mode. The hysterisis effect can be bypassed by forcing the power management unit into active mode without changing the activity count. In this case, the next idle function call will bring the system back to idle mode.

If the software monitor or the hardware monitor indicates inactivity, the power management unit enters the conservation mode. The conservation mode has multiple states which provide different levels of power conservation.

A first state, called a DOZE state, is entered after sensing 50 inactivity by the hardware monitor for a first period of time. A second state, called a SLEEP state, is entered after sensing inactivity by the hardware monitor for a second predetermined time where the second predetermined time is greater than the first predetermined time. A third state, called a 55 SUSPEND state, is entered after sensing inactivity by the hardware monitor for a third period of time greater than the first and second time periods.

Another state is OFF which turns off all power for the computer under predetermined conditions.

During periods of inactivity, power consumption is reduced in different ways, for example, by reducing clock speeds or removing clocks, and/or by removing power, and/or by controlling the refresh frequency to memory.

In accordance with the above summary, the present inven- 65 tion achieves the objective of providing an improved power management method and apparatus.

The foregoing and other objects, features and advantages of the invention will be apparent from the following detailed description in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 depicts a block diagram of a computer with the power management unit of the present invention.

FIG. 2 depicts a block diagram of the power management unit of the FIG. 1 system. 10

FIG. 3 depicts a detailed block diagram of the hardware for the power management unit of FIG. 2.

FIG. 4 depicts a state diagram depicting the multiple states associated with the power management unit of FIGS. 15 1, 2 and 3 as determined by the hardware monitor.

FIG. 5 depicts a representation of operation for various states as a function of the activity measurement.

FIG. 6 depicts a state diagram depicting switching to conservation mode (DOZE or SLEEP state) operation under 20 control of the software monitor.

FIG. 7 depicts a state diagram depicting the sequencing which forces to the ON state during an activity window period under control of the software monitor.

FIG. 8 depicts a representation of operation for a spreadsheet application program.

FIG. 9 depicts a representation of operation for a wordprocessing application program.

FIG. 10 depicts a representation of operation for a windowing application program.

DESCRIPTION OF THE PREFERRED **EMBODIMENTS**

Computer System-FIG. 1

In FIG. 1, computer 3 is typically a small, batterypowered computer such as a "notebook" computer. The computer 3 includes a CPU 4, a CPU bus 5, a plurality of I/O controllers 6-0, ..., 6-n where "n" is a constant equal, for example, to 7. Connected to the controllers 6-0 through 6-n are plurality of peripheral devices 7-0, ..., 7-n, respectively. The controllers and peripheral devices 6 and 7 typically include a keyboard, a display, a hard disk drive, a modem, a printer, and similar devices. Each of the controllers 6-0 45 through 6-n connects to the conventional computer bus 5.

Also connected to the bus 5 is the memory, which in one particular embodiment is DRAM random access memory 11. The memory 11, when of the type requiring refresh, is refreshed with *RAS and *CAS lines 29 under control of the PC controller 13 which provides *PCRAS and *PCCAS signals on lines 30 to power management unit 15 including a hardware monitor 79 and a software monitor 80. The I/O devices are separately powered through switch unit 22 and switches 22-0, ..., 22-n by the VCC power from power supply 9 which receives power either from the battery 10 or an AC source 14. Power supply 9 is of a conventional type which supplies a low battery signal LB, a low-low battery signal LLB, and an AC power signal ACPWR to power management unit 15.

The computer 3 typically includes as software an operating system adapted to control the computer system and to control operations during application program execution. Computer 3 functions to execute application programs such as word processing, spreadsheet and data base management programs. Computer 3, during the execution of application programs, is under control of a software operating system.

35

40

60

The operating system manages the different system parts and resources including the I/O devices 6 and 7. For example, during the execution of an application program when the CPU wishes to check to determine if any key has been depressed on a keyboard I/O device, the CPU 4 through a 5 subroutine call to the operating system requests the operating system to execute a subroutine to perform a keyactuation detection task. Since the operating system performs many similar calls to the operating system, these calls represent detailed information about many activities within 10 the computer system.

In FIG. 1, the computer 3, through the CPU 4, issues control and address signals on the bus 5 which define the overall computer address range for computers including the sets of address ranges for all of the memory, I/O and other ¹⁵ devices connected to the bus 5. Whenever any of the peripherals 7-0 to 7-n are to be accessed for data to be transferred over the bus 5, the address of the corresponding I/O controller 6-0 to 6-n (either by unique address lines or unique address lines in combination with control lines) ²⁰ specifies the addressed one of the I/O controllers 6 and corresponding peripheral 7.

Similarly, memory 11 has locations addressed by a set of addresses on bus 5 within a memory address range. Some of the addresses in the range of addresses for memory 11 are ²⁵ typically allocated and reserved only as a set of video memory addresses. Whenever the video memory region 8 of memory 11 is to be addressed, address appears on bus 5 within the set of video memory addresses.

The computer system of FIG. 1 includes a power management unit 15 having a software monitor 80 and a hardware monitor 79 for monitoring activity of the computer system. The power management unit 15 is connected to the bus 5 to sense activity, using hardware monitor 79, on the bus 5 and is connected to the CPU 4 (executing the operating system and the software monitor 80), the power supply 9, the memory 11 and PC controller 13 for controlling power management.

The power management unit 15 of FIG. 1 operates to $_{40}$ cause the computer system to enter the power conservation mode after sensing inactivity by the hardware monitor 79 or by the software monitor 80 and to enter the active mode after sensing activity or other conditions.

The hardware monitor **79** monitors the hardware to detect inactivity. The hardware monitor **79** typically is circuitry for detecting inactivity independently from the software and the software monitor **80**. For example, the hardware monitor **79** senses predetermined address ranges, such as an I/O address range and a video memory address range, and monitors the activity of addresses by the CPU to addresses within these ranges. If no data transfers occur within the specified address ranges for predetermined periods of time, then a power control mode is entered to conserve power in the computer system.

The software monitor 80 monitors the activity of the operating system or other software in the system. The software monitor 80 typically is a software module linked, for example, to the operating system at boot time for monitoring subroutine calls to the operating system.

By using a software monitor 80 and a hardware monitor 79. the power management unit 15 decides exactly when to enter into power conservation mode and active mode without unnecessarily sacrificing system performance.

The power conservation mode includes a number of 65 activity states. A first state, called a DOZE state, is entered after sensing inactivity for a first period of time by the

hardware monitor or when an idle threshold is exceeded as determined by the software monitor. A second state, called a SLEEP state, is entered after sensing inactivity by the hardware monitor for a second predetermined time where the second predetermined time is greater than the first predetermined time or when the activity measurement sensed by the software monitor exceeds the idle threshold. A third state, called a SUSPEND state, is entered after sensing inactivity for a third period of time greater than the first and second time periods. Another state is OFF which turns off all power for the computer under predetermined conditions.

After having entered one or more of the activity states of the conservation mode, the power management unit switches back to the active mode when activity is sensed by the monitors.

Power Management Unit-FIG. 2

In FIG. 2, a block diagram of the power management unit 15 of FIG. 1 is shown. The power management unit includes a hardware monitor 79 (including an activity monitor 16 and a timer unit 24), a software monitor 80, a state control unit 23, a power control unit 17, a clock control unit 18, and a refresh control unit 20. The hardware monitor 79 (using activity monitor 16) analyzes the address activity on the system bus 5 to provide activity information used to control power management. The timer unit 24 times the activity information sensed by the monitor 16. The state control unit 23 controls the changes among different power consumption states to achieve power management.

The power control unit 17 controls the switches $22-0, \ldots$, . . , 22-n of FIG. 1 as a function of the activity sensed by activity monitor 16 and the state determined by state control unit 23.

The clock control unit 18 controls the distribution of and/or the frequency of the CPU and other clocks as a function of the activity sensed by the activity monitor 16 and the state determined by state control unit 23.

The refresh control unit 20 controls the refresh of the RAM memory 11 of FIG. 1 at a rate which is determined by the activity sensed by the activity monitor 16 and state control unit 23.

The power management unit (PMU) 15 is provided to manage power and reduce, over time, the overall power consumption of computer 3. This management is accomplished using an activity monitor 16 to detect periods of system inactivity. During periods of inactivity, power consumption is reduced by reducing clock speeds or removing clocks through clock control unit 18, and/or by removing power through power control unit 17, and/or by controlling the refresh frequency through refresh control unit 20. Standard and slow refresh DRAM support is provided by refresh control unit 20. Inputs are provided to the power management unit 15 which will allow power on or off commands from external sources such as a pushbutton, modem ring indicator, or read-time-clock (RTC) time of day alarm.

Hardware Monitor Generally-FIG. 3

60

Referring to FIG. 3. the power management unit (PMU) 15 includes the hardware monitor 79 (activity monitor 16 and timer unit 24) which is designed to operate with minimal system requirements and without software support. Power management occurs in response to the hardware monitor independently of any operating system (DOS) or application program support.

In FIG. 3, the PMU 15 has its own power-on reset signal (*RESET) which is produced by a VCC power detector 71. separate from any other reset signal of computer 3, and upon initial power-on, the registers of the power management unit 15 are initialized to preestablished default values to provide 5 basic functionality without need of any software.

While the hardware monitor 79 and the power management unit 15 are provided FIG. 3 as a hardware embodiment, a software embodiment of the hardware monitor 79 is described in the program listing of TABLE 1. Using the 10 program listing of TABLE 1 executing in the CPU 4, power management, using a software embodiment of a hardware monitor, occurs under program control.

In accordance with the operation of the hardware monitor 79. a predetermined set of address ranges on bus 5 is ¹⁵ monitored by power management unit 15 as part of the power management operation. For example, the predetermined set of address ranges monitored for power management typically includes all of the I/O address range, that is, 20 the addresses of the I/O controllers 6-0 through 6-n and the video memory address range for the video memory locations 8 within the memory 11. Of course, other address ranges can be added to or used as the predetermined set for power management. The set of address ranges including the video memory and the I/O address ranges has been found to 25 provide excellent information for controlling power management.

The hardware monitor 79 senses the activity of addresses on the bus 5. Whenever addresses within the predetermined set of addresses are not present on the bus 5 for predetermined time periods, the power management unit 15 responsively switches power consumption states and controls the consumption of power by different parts of the computer 3.

The power management unit 15 has four main operating 35 states, namely, ON, DOZE, SLEEP, and SUSPEND, and a fifth state which is OFF. The five power management states, under control of the hardware monitor 79, are shown by the state diagram of FIG. 4. The activity monitor 16, external inputs (EXT, RESET), and the timeouts of timer unit 24 $_{40}$ generally control the transitions between states in the state control unit 23 as shown in the state diagram of FIG. 4. The CPU 4 of FIG. 1 may also command the PMU 15 to enter any state. The commands from the CPU 4 typically derive from execution of the software monitor 80, but may derive 45 from other CPU 4 commands.

In FIG. 3, each of the four active states (not OFF) has an associated PWR register which indicates in one embodiment which of eight power control outputs VP[0...7] on lines 33 will be active during the state. More generally, any 50 number, (n+1), outputs VP[0. ...n] can be employed. The PWR registers in power control unit 17 are PWRON register 57. PWRDOZE register 58. PWRSLEEP register 59 and PWRSUSPEND register 60 as shown in FIG. 3. A power control multiplexer 76 selects the eight outputs from one of 55 following CHART 1. the registers 57 through 60 corresponding to the current state on STATE lines 34 from unit 23, and these eight outputs drive the VP[0...7] power control outputs from EXOR unit 35. Also, the CPU 4 of FIG. 1 can write, under program control, to any of the PWR registers 57 through 60 to control 60 which of the I/O devices 6 and 7 are powered at any time.

To turn an I/O device on, the corresponding bits in the PWR registers 57 through 60 for the state(s) in which they are to be on is typically high. The POLARITY register 61 specifies the actual polarity of each output VP[0...7] 65 required to turn the associated one of the switches 22-9, . . ., 22-n on and thereby supply power to the I/O devices 6 and

7. The default value of the POLARITY register is 03h, which implies a logic low to turn on VP[2...7], which will typically control logic switches 22 with low-true output enables (for example, switches 22 typically include a PNP transistor in the VCC line from power supply 9) and high to turn on the LCD, VP[0], and EL backlight, VP[1], power. The value of the $VP[0 \dots 7]$ bits just prior to the polarity control by EXOR 35 may be read back through the OUT-PUT register 62 to CPU 4 over bus 5.

The system clock oscillator signal CLKI is connected to the CPU Clock Control block 49 to produce the CLKOUT. From there CLKOUT, as controlled by PMU 15 and control block 49, drives CPU 4. The CLKOUT clock can be stopped for static CPU's, or reduced automatically by a divisor specified in the CLOCK field of control register 53 during DOZE and SLEEP states. CLKI is passed through unchanged to CLKOUT in SUSPEND state.

Detailed implementations of the various monitor, control and logic blocks of FIG. 3 will be clear from the following detailed description. Additionally, a software embodiment of the hardware monitor 79 including logic and control functions equivalent to those in the hardware embodiment appears as the Program Listing of TABLE 1.

Software Monitor Generally

The software monitor 80 of FIG. 2 includes a power management software module linked into the operating system, for example, during boot up time. One embodiment of the module appears as the program listing of TABLE 2.

The software monitor 80 monitors all the function calls to the operating system. Every time an idle function call is made, the activity measurement, AC(t), is incremented and then checked against thresholds. The incrementing is algebraic by the amount of D_a , a positive DOS call number, or D_i, a negative DOS call number.

If the activity measurement, AC(t), is below the idle threshold, T_H , and the system is in the active mode, no action will be taken. However, if the activity measurement, AC(t). is above the idle threshold, T_H , the power management software will check the current system status and if in the active mode, will switch to the conservation mode.

The activity measurement, AC(t), is given by the following Eq. (1):

$$\Sigma |D_o(t) + D_t(t) = AC(t)|$$
 Eq. (1)

where.

30

 $D_{a}(t)$ =Active DOS call numbers as a function of time D_i(t)=Idle DOS call numbers as a function of time

AC(t)=Accumulated Activity Count of DOS call numbers as a function of time, that is, activity measurement

While all of the interrupts of the operating system may be assigned a D_a or D_i value the following, for example in the

CHART 1

INTERRUPT	CALL NUMBER	TYPE
I16 (keyboard poll)	+12	Di
I10 (video active)	-25	Da
IS (timer)	-25	Da
I14 (communications)	-400	Da

Using the values in CHART 1, each time an interrupt 16 (I16) occurs, the software monitor increments AC(t) by +12 and each time I10 or I8 occurs the software monitor incre-

ments AC(t) by -25. The value of AC(t) is shown for one example of operation in FIG. 5.

Referring to FIG. 5, the value of AC(t) as a function of t is shown. In the example of FIG. 5, the first eight values of t find keyboard polling occurring by the I16 interrupt so that +12 is added to AC(t) for each of the first eight values of t. In FIG. 5, at t=8, the timer interrupt I8 occurs and subtracts -25 from the AC(t) value. Thereafter the keyboard polling continues until the value of AC(t) reaches 128, the value of T_H in the example of FIG. 5. At t=12 in FIG. 5. AC(t) is 10 reset, for example, to 0 when the computer system enters the conservation (idle) mode. At about t=20 in FIG. 5, which may include a long time duration generally indicated by the broken line at about t=15, video interrupt I10 becomes active and starts to add -25 to the AC(t) value until at about time t=35 the value of AC(t) reaches the -256 value of the 15 threshold T_L.

When the value of AC(t) is above T_{H} , then the software monitor is operative to switch the computer system into the conservation mode. Whenever AC(t) is in below the threshold T_L , the software monitor is operative to switch the 20 computer system back to the active mode.

The example of FIG. 5 is only for purposes of representing the manner in which AC(t) is incremented as a function of the positive and negative interrupt call numbers. Of course, other counting methods may be employed. In the 25 program of TABLE 2, after the T_H , value of +128 is reached, the counter is reset to +256 and each value of Da decrements the count until the threshold TL is reached at 0.

The operation which occurs when the value of AC(t)exceeds the threshold T_{H} , is explained with respect to the 30 flowchart of FIG. 6.

In FIG. 6, the value of D (either Da or Di), the interrupt number value, is added as indicated in Eq. (1) to form the accumulation value of the activity measurement, AC(t). This accumulation is indicated by the oval marked D in FIG. 6. 35

Next, the value of AC(t) is compared with the threshold T_{H} . If the value of the summation in Eq. (1) is not greater than the threshold, T_H , then the N no choice is made the loop repeats so that the next value of D is added to the AC(t)activity measurement. For example, in FIG. 5, this activity 40 continues until approximately t=12 in FIG. 5.

In FIG. 5, at about t=12, the activity measurement AC(t) equals or exceeds the threshold T_H and hence the Y output of the comparison connects to the SLEEP state detector. If already in the state, then the Y output will force the computer 45 system to remain in the SLEEP state. If not in the SLEEP state, then the software monitor will force the computer system into the DOZE state.

Note that the FIG. 6 operation will force the computer system into the DOZE or SLEEP state as long as the activity 50 idle threshold, T_H . measurement AC(t) exceeds the threshold T_H . When the threshold T_H has been exceeded, AC(t) is reset and remains reset until another activity event, Da or Di, occurs. In FIG. 5, for example, this occurs at about t=20 when AC(t) begins to count toward T_L .

In addition to the comparison of the activity measurement AC(t) against the upper threshold T_H , the software monitor 80 also compares the value of the activity measurement against the lower threshold T_L. This comparison is represented by the flowchart of FIG. 7.

In FIG. 7, the oval represents the incrementing of the activity measurement AC(t) in accordance with Eq. (1). After each incrementing of the activity measurement, the value of AC(t) is compared to determine if it is less than or equal to T_L . If not, then the N output of the comparison 65 continues the incrementing of the activity measurement for each new value determined in accordance with Eq. (1).

If the activity measurement AC(t) is less than or equal to T_L , then the Y output of the comparison connects the operation to the activity window comparison.

If $AC(t) \leq T_L$ and $AW(t) \leq T_{aw}$, then the FIG. 7 operation switches to the ON state.

If $AC(t) \ge T_H$, then test sleep state. where.

> Тн ≥ Kı ≦ K_2 Tt. Idle Threshold Тн = Activity Threshold Tı. = K₁ = 128 K_2 Ξ -256

Combined Hardware Monitor and Software Monitor Operation

If the system is in ON state and AC(t) is greater than or equal to T_H , the power management software monitor will bring the system into DOZE state. If the system is already in DOZE or SLEEP state, no further action will be needed. Similarly, the activity count. AC(t), will be decremented every time an active function call. Da, is made. The activity count is then used to compare with the active threshold. If the count is higher than the active threshold, T_H , then the power management software monitor 80 will force the system into the power conservation mode (DOZE or SLEEP) per the FIG. 6 operation regardless of the status of the hardware monitor 79. If the activity count is equal to or less than the active threshold, T_L , then the system will be programmed into the ON state.

The ON state can also be entered if the hardware monitor 79 detects a predetermined set of address ranges on bus 5. For example, the predetermined set of address ranges monitored for power management typically includes all of the I/O address range, that is, the addresses of the I/O controllers 6-0 through 6-n, and the video memory address range for the video memory locations 8 with the memory 11. Of course, other address ranges can be added to or used as the predetermined set for power management. The set of address ranges including the video memory and the I/O address range has been found to provide excellent information for controlling power management.

After entering the ON state, the power management unit will continue to be in the ON state until any idle function call detects the activity count has reached or gone beyond the

There are application programs such as Microsoft's Windows described in connection with FIG. 10 that do not use the DOS idle function calls and therefore the system would never go into the DOZE state through operation of the software monitor 80. Therefore, a watch dog timer is built into the power management software monitor to monitor the absence of idle function calls as indicated in connection with FIG. 7. If a time period greater than T_{aw} as shown in the flow chart in FIG. 7 has been exceeded without any idle function 60 call being made, then it is assumed that the application program bypasses DOS and goes directly to the hardware.

During the T_{aw} time period (see FIG. 7) the power management unit will be forced into the ON state until detection of activity for predetermined period of time, Taw. This period, T_{aw} is normally more than a minute in order not to affect the system performance. There is no power saving during the time out period, Taw, even if the CPU is actually idling. After the T_{aw} time period, the hardware monitor 79 will take over completely.

In most cases, application programs go through DOS to perform I/O operations. The power management software monitor 80 keeps track of all the operating system function 5 calls. If the accumulative count of all active and idle function calls is greater than the upper threshold, T_{H} , then the system is assumed to be inactive. The power management software monitor will program the power management unit to DOZE state only if the system is still in ON state. The 10 computer 3 will enter DOZE state without waiting for the ON state timer to expire and therefore maximizes the power saving of the system. If computer 3 is already in DOZE or SLEEP, no action will be needed from the power management software monitor until the system becomes active 15 again.

In the software monitor 80, inactivity is determined by detecting how many active or idle function calls an application makes within some time period. In the IBM PC DOS 20 environment, the activity status is checked no less frequently than every 50 milliseconds. There are 256 IBM PC DOS function calls and each is labeled as idle or active with a corresponding positive or negative number. A positive number is assigned to an active function call and a negative number to an idle function call. The power management ²⁵ software module keeps a running total of the accumulated value of the function call numbers as the function calls are made. Whenever a function call is made, (either active or idle), the power management software module algebraically 30 adds the number to the accumulated value and decides whether the system is active or not by comparing the magnitude of the accumulated value with a function call threshold. The function call threshold for determining activity is a variable depending on the computer system speed. 35

To prevent the system from oscillating between the active and idle state due to minor changes in system activity, hysterisis is provided by using active, T_L , and idle, T_{H} , function call thresholds. The accumulated total is clamped at T_H after it reaches the active thresholds T_H or T_L as the case **4**0 may be. The active and idle thresholds are typically unequal (128 and -256) so that the entry and exit from conservation (idle) mode is biased. For example, in order to have the system enter the idle mode quickly and thereby to reduce power consumption, the active threshold is set with a 45 threshold number (128) greater than the idle threshold number (-256). Also, functions that require immediate attention are assigned numbers large relative to the active and idle thresholds so that a single occurrence of the function call (for example, I14=-400) will force the accu-50 mulated count over the active threshold (T_L =-256) and thus force the system to be in the active mode. The hysterisis effect can be bypassed by forcing the power management unit into active mode without changing the activity count. In this case, the next idle function call will bring the system back to idle mode.

If the software monitor 80 or the hardware monitor 79 indicates inactivity, the power management unit enters the conservation mode which has multiple states with different levels of power conservation.

The hardware monitor 79 works in conjunction with the software monitor 80 linked to the operating system during boot up time. The state control unit 23 is controlled by the timer unit 24 and power management software module 100. timer unit 24 whenever inactivity is detected in the operating system level. Since this can be done in a much finer

resolution than the hardware monitor 79, the combined software and hardware monitor maximize power saying without any degradation in system performance.

Power Management Unit Detail-FIG. 3 Line List

In FIG. 3, the following lines and functions are defined for the connections output (O) from and input (I) to the PMU 15 of FIGS. 1 and 2.

Name	Туре	Function
SA[09]	I	System Address on bus 5
SD[07]	I/O	System Data on bus 5
VP 0	0	LCD power control
VP1	0	EL backlight power control
VP[27]	0	Peripheral power control
*RAS	0	*RAS for DRAM
*CAS	0	*CAS for DRAM
*PCRAS	I	*RAS for DRAM
*PCCAS	I	*CAS for DRAM
*VCS	I	Video RAM chip select
*IOR	I	I/O Read
*IOW	I	I/O Write
*S1	I	Status, low indicates read or
		read operation
AEN	I	DMA enable
INMI	I	NMI input from user system
NMI	0	NMI output to CPU
INTR	I	Int request output of computer
DRQ[03]	I	DMA requests which could occur in DOZE or SLEEP
*DACK0	I	Indicates refresh DMA cycle
EXT	I	External command input (button)
RI	Ι	Ring indicator from modem
RTC	I	Alarm output from RTC
CLKI	I	CPU clock input
CLKOUT	0	Clock out to CPU
LB	I	Low battery detect, first warning
LLB	I	Low battery detect, second warning
ACPWR	I	AC power good input
*RESET	I	External RC required for reset
*REFRSEL	0	Low when PMU controls DRAM refresh
OSC	I	Xtal osc output
CLK1IN	ī	Clock 1 in for switched clock 1 out
CLKIOUT	ō	Switched clock 1 out
CLK2IN	I	Clock 2 in for switched clock 2 out
CLK2OUT	0	Switched clock 2 out
LBPOL	I	Low battery polarity select
STATIC_CPU	I	Connect to Vcc if CPU is static
VCC		Power
VSS		Ground

Registers

In FIG. 3, the PMU 15 includes a number of registers accessed for read or write by CPU 4 over bus 5 via an index register addressing scheme. When not accessed by CPU 4. 55 for example, after a power on detection by detector 71, the registers are all initialized to a default state. When accessed by CPU 4, an index value is first written to the index register 50 from bus 5 and the index value is decoded by decoder 70 to select one of the registers of PMU 15 for access to bus 5 to receive or send information from or to CPU 4. The index register 50, after an index write, is changed to point to another register to be accessed. When reset, the index register is not active to enable any PMU 15 register. This is The power management software will override the hardware 65 a safety feature to help prevent applications executing on the CPU 4 from inadvertently accessing PMU 15 registers. All registers may be read and written over bus 5.

60

45

50

55

65

The PMU 15 data registers are:

Data Register (Ref. N	(oFIG. 3)	Index Decode		
STATUS	51	00H		
SUPPLY	52	0 2H		
CONTROL	53	04H		
ACTMASK	54	06H		
NMIMASK	55	08H		
OSC	56	OAH		
PWRON	57	OCH	1	
PWRDOZE	58	OEH		
PWRSLEEP	59	10 H		
PWRSUSPEND	60	12H		
POLARITY	61	14H		
OUTPUT	62	16H		
DOZE	63	18H	1	
SLEEP	64	1A H	-	
SUSPEND	65	1CH		
LCD	66	1EH		
EL	67	20H		

Status Register		
Bit	Name	Function
D7	RESUME	Resuming from SUSPEND (warm start)
D6	WU1	Wakeup code MSB
D5	WU0	Wakeup code LSB
D4	NMI2	\
D3	NMI1	> NMI cause code
D2	NMI0	1
D 1	STATE1	State MSB
D 0	STATE0	State LSB

In register 51, only D0 and D1 are affected by a write. The CPU 4 can write the state code to this register to put the PMU in another state. Writing OFFh puts it in the OFF state. The NMI cause, state and wakeup codes are decoded as follows:

Code Wakeup	NMI Cause	Code	State	Code	Cause
000	None, or INMI	00	On	00	
001 imput	EXT input	01	DOZE	01	ЕХТ
010 imput	LB	10	SLEEP	10	RTC
011 input	LLB timeout	11	SUSPEND	11	RI
100 101	SLEEP timeout SUSPEND timeout				

*RESET sets STATE[0..1] and clears all other bits.

Supply Register

This register 52 is read only. D[0 . . . 2, 5] are driven directly by the input lines. Bit D3 is set when system activity is detected and is cleared when this register is read.

Bit	Name	Function
D5	STATIC_CPU	1 = Static CPU (clock stops in DOZE)
D4	DRAMRDY	1 = CPU controls DRAM (same as *REFRSEL)
D3 D2	ACTIVITY LLB	System activity present Low battery 2 (second warning)

14	14
----	----

contin	hour	
conui	Inca	

	Bit	Name	Function
5	D1	LB	Low battery 1 (first warning)
	D0	ACPWR	AC power input in range

Control Register

	Bit	Name	Default	Function
	D7		0	
	D6	RING2	0	1
15	D5	RINGI	0	> Number of RI pulses required
15				for turnon
	D4	RINGO	1	/ default = 1
	D3	STATIC_CPU	0	For static CPU's
	D2	SLOW	0	Clock runs slow in ON
	D1	CCLK1	1	CPU Clock divisor, DOZE and SLEEP
	DO	CCLK0	0	/ default divisor = 4

In register 53, the RING $[0 \dots 2]$ bits are used to set the number of RI pulses required for turnon. The default value 25 is 1 so that only one pulse is required for turnon. If set to 0, RI is disabled. State logic 23 has conventional logic for detecting and counting RI pulses from a modem, one of the I/O peripherals 7-0 to 7-n. D3 is only used for static CPU's. SLOW indicates reduced clock speed operation in On. The CCLK[0...1] bits select the clock divisor for CLKOUT in SLEEP and DOZE states, and in ON if SLOW is set, according to the table.

35	CCLK[01]	Divisor	
	0	1	
	1	2	
	2	4	
40	3	8	

ACTMASK Register

Bit	Name	Default	Function
D7		0	
D 6	MSK_VIDM	0	Mask access to video memory
D5	MSK_DMA	0	Mask all DMA activity
D4	MSK_P63	1	Mask access to port 63h
D3	MSK_PIC2	0	Mask access to port A0h, A1h
D2	MSK_RTC	1	Mask access to port 70h, 71h
D1	MSK_KBD	0	Mask keyboard (port 60H, 64H
DO	MSK_IO	0	Mask access to all ports not maskable by D[25]

The activity monitor ACTIVITY output is the logical OR of all unmasked activity sources. This register 54 affects only the ACTIVITY output. Refresh DMA cycles 60 (*DACKO low), interrupts, or accesses to the PMU 15, never affect the activity monitor 16.

NMIMASK Register

This register 55 masks the various NMI sources. In the default state only the INMI input can generate NML

35

40

55

Bit Default	Name	Function	
D6	OS2	Mask INMI input	0
D5	MSK_SUSPEND	Mask SUSPEND timeout	1
D4	MSK_SLEEP	Mask SLEEP timeout	1
D3	MSK_LLB	Mask LLB input	1
D2	MSK_LB	Mask LB input	1
D 1	MSK_EXT	Mask EXT input	1

OSC Register

Bit	Name	Default	Function	1
D7	OSCDIV3	1	1	_
D6	OSCDIV2	1	OSC input divisor -1	
D5	OSCDIV1	0	default code = 1101 (divisor = 14)	
D4 D3	OSCDIV0	1	i	20
D2	SLWREF	0	Slow refresh DRAM	
DI	RASWIDTH1	0	*RAS pulse width MSB	
D 0	RASWIDTH0	0	*RAS pulse width LSB	

Referring to register 56. OSCDIV[0...3] plus one is the OSC frequency in MHz, except for OSCDIV $[0 \dots 3]=13$, the default, indicates 14,318 MHz. SLWREF is set when slow refresh DRAM is used. RASWIDTH[0...1] indicates the width of the *RAS pulse in units of OSC periods. The 30 default value is 0 which disables refresh in SUSPEND state. and no RAS/CAS is generated. Values of 1 to 3 indicate 1 to 3 OSC periods.

PWR Registers

The bits D[0...7] in these registers 57 through 60 correspond directly with the power control outputs VP[0... . 7]. In a particular state, the corresponding PWR register outputs control the VP lines 23. The exception is VP0 and VP1 which are LCD and EL power, respectively. These outputs are AND'ed in AND gates 41 and 42 with the LCD and EL timer outputs prior to driving the lines 33. All bits are then exclusive NOR'ed in gates 35 with the POLARITY register 61. and the result drives the lines 33. The default 45 values for these registers are as follows, where 1 indicates that the controlled device is on:

PWRON	FFh	
PWRDOZE	FFh	50
PWRSLEEP	OFh	
PWRSUSPEND	OOb	

POLARITY Register

This register 61 controls the polarity of the VP outputs. If a logic low is required on a VP line to turn the external device on, the corresponding bit in the POLARITY register 61 must be low. If a high is required, set the bit high. The $_{60}$ default value is 03h.

Timer Registers

The nonzero value loaded into one of the timer registers 63 through 68 is the actual timeout minus one. A zero 65 disables the timeout. Therefore a 4 bit timer can be set for a timeout from 1 to 15 time units. Reading a timer register

returns the value that was last written to it, not the actual time remaining. The default values are tabulated below:

5	Timer	Range	Default
	DOZE	1-15 sec	5 sec
	SLEEP	1-15 min	2 min
	SUSPEND	5-75 min	0 (disabled)
	LCD	1-15 min	TBD
	EL	1-15 min	TBD

OUTPUT Register

The OUTPUT register 62 is a read only register. For each ¹⁵ VP[0...7] output that is on, the corresponding bit in the OUTPUT register will be set.

The control and logic functions for the activity monitor 16, the state logic 23, the NMI logic 21, and other components of FIG. 3 are conventional logic circuits for implementing the logic and control functions hereinafter described or alternatively are the software logic of TABLE 1.

ON State

Referring to FIG. 4, the ON state is entered from the SUSPEND or OFF state when the *RESET input is low, and also when one of EXT, RTC or RI goes high if ACPWR is true or LB is false. It is entered from DOZE or SLEEP when the activity monitor 16 detects activity with addresses in the predetermined address set. In the ON state encoded on lines 34, all power control outputs VP[0. . . n] will be controlled by the PWRON register 57. Upon entering the ON state, the DOZE timeout timer 63 will be retriggered. The LCD and EL timeouts in timers 66 and 67 will be retriggered when entering the ON state from SUSPEND or OFF. The retrigger lines from STATE logic 23 to the timers are not shown in FIG. 3 for clarity.

In FIG. 3, the STATE logic 23 recieves the CPU data bus D(0...7) from bus 5 for receiving state commands issued by the software monitor 80 of TABLE 2. The STATE logic also receives the address detection line 76 from activity monitor 16 which enables the STATE logic 23 to receive the state commands from the software monitor when addressed over the bus 5.

If the SLOW bit in the control register 53 is false, the CLKOUT rate on line 28 will be full speed. If the SLOW bit is true, CLKOUT will be as specified by the CCLK[0,1] bits in register 53. This clock control allows the user to save power, for example, when running non-computationally intensive applications such as word processing.

DOZE State

The DOZE state is entered from the ON state when the activity monitor 16 has not detected activity and therefore has not provided the ACTIVITY signal within the time, T1, specified by the DOZE timer 63. In the DOZE state encoded on lines 34, the power control outputs VP[0...7] from unit 17 are controlled by the PWRDOZE register 58. If a non-static CPU 4 is used, the clock on line 28 will be slowed as specified by CCLK[0,1] in register 53.

If a static CPU 4 is used, CLKOUT on line 28 will stop in the low state immediately following a non-DMA memory read instruction, as indicated by *S1 going high while *AEN is low, so that no chip select will be low. If INTR goes high, CLKOUT will be enabled until after EOI is written to the

interrupt controller with INTR false. If INMI goes high, CLKOUT will be enabled. If an internally generated NMI occurs, CLKOUT will be enabled until the NMIMASK register 55 is read. If any DRQ goes high, CLKOUT will be enabled until after the next memory read instruction with 5 AEN and all DRQ inputs false. The enable request functions for INTR, INMI, internal NMI and DMA are separate and CLKOUT is enabled when any event requests it, so that an interrupt handler in CPU 4 will run to completion even if it is interrupted by a DMA request. These enable request 10 functions are independent of the activity monitor and the ACTMASK register 54. Enabling CLKOUT does not cause the PMU 15 to leave DOZE, unless the activity monitor 16 is subsequently triggered. If this trigger occurs, the PMU 15 will enter the ON state and the enable request logic will be 15 cleared.

SLEEP State

The SLEEP state is entered when the PMU 15 has been in the DOZE state for the time, T2, specified by the SLEEP ²⁰ timer 64 and no ACTIVITY signal has occurred. In the SLEEP state, the CLKOUT operation is the same as in DOZE. The power control outputs are controlled by the PWRSLEEP register 59.

Alternatively, the PMU can be programmed to generate ²⁵ NMI and remain in DOZE state instead of automatically entering SLEEP.

SUSPEND State

The SUSPEND state is entered when the PMU 15 has been in the SLEEP state for the time, T3, specified by the SUSPEND timer 65 or when a power check detects low battery signals, LB or LLB. The SUSPEND state is entered after these conditions only when the CPU 4 writes the code 35 for SUSPEND to the STATUS register 40 and this operation requires software support because in SUSPEND the CPU operation is affected. In SUSPEND operation, CLKOUT is the same as CLKI. The power control outputs are controlled by the PWRSUSPEND register 60. In SUSPEND, the CPU 4 and the device (for example, a switch) which generates the system reset signal must be powered off. Only activity on the EXT, RI or RTC inputs can cause an exit from SUSPEND, and the new state after exit will be ON. When the reset circuit power is restored, it will reset the CPU 4, which will 45 then execute a warm startup routine in a conventional manner. DRAM refresh may be enabled in SUSPEND. If DRAM refresh is not enabled, the PMU 15 does not need OSC from unit 43 in SUSPEND, and gates it off internally to minimize OSC power consumption. The OSC output will 50 stay low. The bus interface is inhibited, and the data bus 5 is tristated.

OFF State

The OFF state is entered when the CPU 4 writes the code 55 of OFF (OFFh) to the STATUS register 51. It is also entered 5 seconds after the EXT input goes high if the NMI is not serviced.

The OFF state is meaningful only when the PMU 15 is powered from a battery while the rest of the computer 3 is 60 turned off. This type of power connection is necessary only if the PMU 15 must awaken the system from the OFF state by activating VP outputs on lines 33 in response to transitions on the EXT input. If this function is not required, then the PMU 15 may be powered off when the system is 65 powered off, and the OFF state as described below is not required.

In the OFF state, all outputs from the PMU 15 are either low or tristated, and all devices other than PMU 15 in the computer 3 are powered off. Any inputs will have pulldowns so that floating inputs, if any, will not cause increased power dissipation. Only activity on the EXT, RI or RTC inputs can cause an exit from OFF, and the new state will be ON. The bus 5 interface is inhibited and data bus 5 is tristated.

Activity Monitor

The activity monitor 16 includes an address detector 73 which receives addresses from bus 5 representing the address activity of the CPU 4. The address detector 73 receives, for example, control lines and address lines $SA(0 \dots 9)$ from bus 5 for sensing when those addresses are within the predetermined address set. The predetermined address set is defined, for example, by an address set specified by ACTMASK register 54. The detector 73 compares or masks the address set specified by register 74 with the addresses on bus 5 and provides an address detect signal on line 76 to the logic 77. The logic 77 receives the other inputs to the activity monitor 16 and combines them, using conventional logic circuitry, to provide three outputs.

The three outputs provided by activity monitor 16 are produced by conventional logic or by software as shown in TABLE 1. The EXTRIG output is a function of keyboard activity only and is used to retrigger the EL backlight timer 67. The LCDTRIG output is true for keyboard activity or video memory writes, and retriggers the LCD timer 66. The ACTIVITY output is an OR function of a programmable selection of different activities specified in the ACTMASK register 54. When active, this output returns the PMU 15 to the ON state and retriggers the DOZE timeout timer 63. The activity monitor 16 does not produce the ACTIVITY output in response to accesses to the registers of PMU 15.

OSC Programmability

The OSC frequency of refresh control unit 20 provides the timebase for the timers and the refresh for DRAM memory 11. The PMU 15 may be programmed to accept a range of OSC frequencies. The OSC frequency of oscillator 43 is fed to a counter 44 which divides it by a divisor which is programmed in the OSC register 56. The programmable counter output of divider 44 is divided to produce 256 Hz which is used by the refresh control logic 48. Further dividing in divider 46 produces 32 Hz for slow refresh to refresh control logic 48, and 8 Hz and 1/(7.5) Hz for use by the timers 63. 64, 65 and 68.

Timers

There are six timers in the PMU 15. namely. DOZE timer 63. SLEEP timer 64. LB (low battery) timer 68. SUSPEND timer 65. EL (backlight) timer 66. and LCD timer 67. Each of the six timers a 4-bit register loadable by CPU 4 over bus 5. Setting a timer register to 0 disables it; setting it to a nonzero value enables it. If enabled, certain timers are triggered by the transition to the ON state. Individual timers are also triggered by events specific to their functions. Some timers are retriggerable, timing out at a programmable time following the last trigger.

The DOZE timer 63 is programmable from 1 to 15 seconds with a resolution of 1 second, and the SUSPEND timer 65 is programmable from 5 to 75 minutes with a resolution of 5 minutes. All other timers are programmable from 1 to 15 minutes with a resolution of one minute. There is a quantization error associated with retriggering any timer. This error is a quantization error associated with retriggering the retriggering and the second s

20

any timer. This error will cause the actual timeout to be up to 1/8 of the resolution of the timer longer (but never shorter) than the programmed value. The error does not vary with the programmed value.

The LCD timer 66 and the EL timer 67 are retriggerable. The timer outputs are AND'ed in AND gates 41 and 42 with the power control bits selected by the power control multiplexer 76 according to the current PMU state to control the LCD (VP0) and EL (VP1) power control outputs to EXOR 35. This operation provides the flexibility to turn the EL and LCD outputs off when the associated timers 66 and 67 time out, or to control the outputs in any PMU powermanagement state under control of multiplexer 76.

The DOZE timer 63 is retriggerable and is triggered by the activity monitor ACTIVITY output in the ON state, and 15 triggers the transition to DOZE state when it times out.

The SLEEP timer 64 is triggered when the DOZE state is entered and is cleared when the DOZE state is exited. Timer 64 either generates NMI or triggers the transition to SLEEP state when it times out.

The SUSPEND timer 65 is triggered when the SLEEP state is entered and is cleared when SLEEP is exited. If unmasked, an NMI will be generated when it times out.

The LB timer 68 is enabled when ACPWR is false (no AC power). Timer 68 is triggered when LB is first detected. If unmasked, NMI is generated by the LB timer 68 output once per minute when it times out, until a period of one minute elapses during which LB remains continuously false. The NMI cause will be identified as an LB or LLB interrupt. Software can maintain a counter and display a message once 30 per X interrupts. It can also monitor LLB and shut the computer down after Y interrupts. It can also monitor LLB and shut the computer down after Y interrupts with LLB true.

NMI

The PMU unit 15 OR's together a number of internally generated NMI requests to produce the NMI output on line 27. These requests can be masked by bits in the NMIMASK register 55. The INMI input comes from conventional exter-40 nal NMI-generating logic such as a parity detector, and can be OR'ed with the internal NMI requests to generate NMI when unmasked by the OS2 bit in the NMIMASK register 55. The NMI output on line 27 generally goes to the CPU NMI input, except on OS2 systems where it must go to an 45 IRQ. The NMI CAUSE code bits in the Status register 40 indicate the cause of the NMI on line 27. An internally generated NMI is cleared by reading the NMIMASK register 55.

NMI may be generated to indicate a low battery when 50 ACPWR is false.

If the MSKSLEEP bit is cleared, the PMU 15 will generate NMI when the SLEEP timer 64 times out and remain in DOZE instead of entering SLEEP.

NMI is also generated when the SUSPEND timer 65 55 ON state. times out. Software can then save status and go to SUS-PEND or OFF state.

A high on the EXT input while not in the OFF or SUSPEND state will generate NMI. Software can then save 60 status and go to SUSPEND or OFF state. If the NMI is not serviced within 5 seconds, the PMU 15 assumes there is no software support for SUSPEND and will turn all power off and enter the OFF state.

Refresh In SUSPEND State

Refresh is enabled by setting the RASWIDTH[0...1] bits in the OSC register 56 to a nonzero value. This enables

OSC to run in SUSPEND mode, and the RASWIDTH value also sets the width of the *RAS pulse in units of OSC clock periods. Slow refresh is enabled by setting SLWREF high. The PMU 15 generates *MRAS and *MCAS signals to mux 32 to refresh DRAM while the CPU is powered off or being reset. When the CPU is active, the *PCRAS, *PCCAS signals on lines 30 from the PC controller 13 are selected by multiplexer 30 to provide the *RAS. *CAS signals on lines 29. *REFRSEL on line 72 will go low to indicate that the 10 PMU 15 is controlling refresh and high for PC controller 13 control.

If enabled, the DRAM refresh outputs are active in SUSPEND. When entering SUSPEND, the PMU 15 immediately generates a burst of 1024 CAS before RAS refresh cycles. A burst of 256 cycles is then repeated every 3.9 ms if SLOWREF is false or every 31.25 ms if SLOWREF is true. After entering the ON state from SUSPEND, the PMU 15 generates bursts of 1024 refresh cycles over 2.9 ms. This operation allows as much time as needed for CPU power stabilization, crystal oscillator startup and CPU reset. When the CPU is ready to take over control of the DRAM, it must poll the SUPPLY register 38 until the DRAMRDY bit goes high. The PMU 15 senses the polling operation as a request from the CPU for DRAM control, and at the end of the first refresh burst following a CPU I/O read of the SUPPLY register 38, the PMU 15 sets *REFRSEL high to return control of the DRAM to the CPU. The DRAMRDY bit is essentially the same signal as *REFRSEL.

The purpose of the bursts when entering and leaving SUSPEND is to eliminate violations of the refresh rate spec when switching between external refresh row address generation (DMA cycles during ON) and internal row address generation (CAS before RAS during SUSPEND).

Pseudostatic RAM refresh is also supported. When 35 *REFRSEL goes low, *RAS can drive *RFSH low for auto refresh mode. The burst refresh will assure that switching between external and internal refresh will not violate the refresh rate spec. Self refresh can also be used by driving *RFSH low when *REFRSEL is low, but other logic will have to generate the refresh burst when entering and leaving SUSPEND, if required.

External Wakeup Inputs

RI is a rising edge sensitive input, to state logic 23 from a modem ring indicator RI output of a peripheral 7. The number of rising edges required for this input to be recognized is specified in bits D[4...6] of the Control register 53. The default is one transition. If these bits are zero, this input is disabled. If enabled, a rising transition on this input will force the PMU 15 to the ON state.

RTC is an edge sensitive wakeup-alarm input from a real time clock in CPU clock control 49 of FIG. 3. A rising or falling transition on this input will force the PMU 15 to the

EXT is a rising edge sensitive input, intended for use with an external pushbutton. A rising transition on this input while the PMU 15 is in OFF or SUSPEND will force the PMU 15 to the ON state. A transition in ON. DOZE or SLEEP will generate NML

EXT is debounced in ON, DOZE and SLEEP in a conventional debouncer circuit 36. A rising edge immediately generates NMI but only if EXT has been sampled low at least twice by a 32 Hz debounce clock from counter 46 65 prior to the rising edge. The debounce clock is derived from OSC 43 and therefore may be stopped in SUSPEND and OFF, so the PMU 15 will not enter these states until the debounce operation is completed. To prevent resuming due to contact bounce on the release of a pushbutton, the PMU 15 will defer execution of a change of state command from the CPU 4 until after the EXT input has been sampled low twice by the debounce circuit 36. This operation is typically 5 transparent to software. For example, if the user presses the button in ON. the PMU 15 will generate NMI, and the CPU will write the command to enter SUSPEND and then execute a halt instruction. Nothing will happen until after the pushbutton is released, at which time the PMU 15 will enter 10 SUSPEND.

Resume and Power On

The PMU 15 has its own private *RESET signal, typically from an external RC network detector 71 which detects VCC. This signal resets only the PMU 15 when power, VCC, is first applied to it. A separate reset signal must be generated by external hardware for the CPU when entering the ON state from SUSPEND or OFF state. At power on, the 20 CPU 4 must read the RESUME bit in the Status register 51. RESUME will be cleared if the startup is a cold start from OFF and will be set to indicate a warm start (resume) from SUSPEND. If RESUME is cleared, the wakeup bits WU[0 ... 1] in the Status register 51 will be zero, otherwise they will indicate which external input caused the resume. The RESUME bit will be cleared after the Status register is read.

Clock Switching

clocks CLK1IN and CLK2IN clocks to output clocks

CLK1OUT AND CLK20UT for peripherals. The CLK1 and CLK2 operations are the same. For example, the CLK1IN is passed to the CLK1OUT output by control 69 in ON and DOZE. When entering SLEEP mode, CLK10UT will stop synchronously in the low state. CLK1OUT will start synchronously when returning to the ON state.

Low Battery Detection

The LB and LLB inputs indicate low battery and low low battery as generated by a conventional battery level detector in power supply 9 of FIG. 1. The polarity of these inputs is programmable by the LBPOL line which can be strapped low or high. If this line is high. LB and LLB are high true. If low, these inputs are low true. The status of the LB and LLB lines after polarity correction can be read in the SUPPLY register 38. A low battery indication can generate NMI.

Power Sequencing

To minimize turnon transients, the turnon of VP1 (EL power) is delayed by 4 to 8 ms after OSC begins clocking. 25 when entering the ON state.

Program Listing

A computer program embodiment of the hardware moni-The clock switch control 69 is provided to switch input 30 tor for the power management unit appears in the following TABLE 1.

.....

TABLE 1 In Software Based Power Management, this routine 3 performs the function of the Timer and Dispatcher It is part of the Timer Interrupt chain, after ; . the timer end of interrupt (EOI) has been sent. 2 ; Checks for system activity and DO2Es/ SLEEPs 3 ; Entry conditions: cli, ds,es,pusha saved, ds=data0p ; This routine contains two threads of code, which execute independently. COUNTER thread: The COUNTER thread checks for the one shot, handles the second and minute counters, and looks at the low battery level, and dispatches the LB event handler. It then looks at the DOZE flag, and if doze is active, returns without changing the activity status; so that the code after the DOZE HLT can function. 1 DOZE thread: ; 2 1 ; The DOZE thread runs when an activity check shows no activity has been present for the entire DOZE timeout. The processor clock entire DOZE timeout. The processor clock is slowed, the DOZE bit is set, interrupts are enabled, and the CPU is put into HLT. When HLT is exited, (18.2 hz) the activity status is checked, to see if DOZE should be terminated. If activity is present, the DOZE flag is cleared and the activity exit is taken. If activity is not present, a test is made for the SLEEP timeout. If the SLEEP timeout has elapsed, SLEEP is entered, after saving the peripheral state. Otherwise, the CPU is halted, and the DOZE loop is reentered, and the cycle continues until terminated by ACTIVITY or SLEEP. : even ;fast... While the invention has been particularly shown and described with reference to preferred embodiments thereof, it will be understood by those skilled in the art that the foregoing and other changes in form and details may be made therein without departing from the spirit and scope of the invention.

What is claimed is:

1. A computer system comprising a power management system and a plurality of computer system circuits including a CPU circuit, a plurality of input/output circuits, a memory circuit, and a system bus which directly connects the CPU circuit with the input/output circuits, said computer system adapted to perform a plurality of activities, wherein said power management system comprises:

- an activity monitor which monitors the activity of the computer system including: 15
 - means for identifying each of said plurality of activities as either an active activity or an idle activity and for associating each of said plurality of activities with a predetermined activity value and with either a first arithmetic sign for activities identified as active 20 activities or with a second arithmetic to said first sign for activities identified as idle activities;
 - an activity count accumulator for accumulating an activity count upon the occurrence of each of said plurality of activities including: means for adding to 25 a stored activity count, upon the occurrence of any one of said plurality of activities, a predetermined activity value associated with said particular activity; and
 - means for comparing the accumulated stored activity 30 count with a conserve threshold and for causing a CONSERVE signal if the accumulated activity count has a predetermined algebraic relationship relative to the conserve threshold; and
 - a mode controller responsive to the activity monitor 35 wherein the mode controller has a plurality of power modes of operation including a first mode and a second mode; and
 - a power control circuit coupled to said activity monitor which in response to the CONSERVE signal transitions from an ON state to a REDUCED state in which the power consumption of the computer is reduced relative to the power consumption in the ON state.

2. The computer system in claim 1, wherein said power 45 control circuit further comprises: a plurality of power switching circuit wherein each power switching circuit controls the power supply to one of the computer system circuits, and wherein each power switching circuit comprises: 50

- a switch which selectively couples a power supply to one of the computer system circuits; a plurality of memory cells associated with the switch including a first memory cell and a second memory cell; a multiplexer coupled to the switch and responsive to the mode 55 controller; wherein the multiplexer couples the first memory cell to the switch in said first mode of the mode controller such that the state of the first memory cell controls whether the switch is open or closed; and wherein the multiplexer couples the second memory 60 cell to the switch in said second mode of the mode controller such that the state of the second memory cell controls whether the switch is open or closed;
- whereby the power supply is selectively coupled to the plurality of computer system circuits and the power 65 consumption of the computer system is controlled in response to the activity of the computer system.

3. The computer system of claim 2 wherein the plurality of memory cells associated with the switch of each power switching circuit can be programmed by the CPU such that the status of the plurality of switches in each of the plurality of modes of operation of the mode controller is programmable.

4. The computer system of claim 3 further comprising a polarity circuit coupled between each plurality of memory cells and each switch wherein the polarity circuit selectively inverts the output of the plurality of memory cells associated with each switch.

5. The computer system of claim 2 wherein the mode controller has at least three modes of operation including a third mode;

- wherein the switch of each power switching circuit is associated with a third memory cell; and
- wherein the multiplexer of each power switching circuit couples the third memory cell to the switch of each power switching circuit in said third mode of the mode controller such that the state of the third memory cell controls whether each switch is open or closed.

6. The computer system of claim 5 wherein the plurality of memory cells associated with the switch of each power switching circuit can be programmed by the CPU such that the status of the plurality of switches in each of the plurality of modes of operation of the mode controller is programmable.

7. The computer system of claim 5 further comprising a polarity circuit coupled between each plurality of memory cells and each switch wherein the polarity circuit selectively inverts the output of the plurality of memory cells associated with each switch.

8. A power management system for use in a computer system comprising a power supply, a plurality of computer system circuits including a CPU circuit, an input/output circuit, and a memory circuit, a system bus which connects the CPU circuit with said input/output circuit and said memory circuit, and a plurality of power control switches which selectively couple the power supply to at least some of the plurality of computer system circuits, said computer system performing a plurality of activities, wherein said power management system comprises:

- an activity monitor which monitors the activity of the computer system including monitoring said system bus which connects said CPU circuit with said input/output circuit and with said memory circuit and generates an activity indicator signal reflective of said monitored activity; said activity monitor including identification logic identifying each of said plurality of activities as either an active activity or an idle activity and for associating each of said plurality of activities with a predetermined activity value for each particular activity having magnitude and algebraic sign, an activity count accumulator for accumulating an activity count based on said magnitude and sign upon the occurrence of one of said activities, and a comparator for comparing the accumulated activity count with a threshold count and for causing said activity indicator signal if the accumulated activity count has a predetermined algebraic relationship relative to the threshold count;
- a mode controller establishing the mode of operation of said computer and responsive to the activity indicator signal of said activity monitor and having a plurality of modes of operation; and
- a power switching circuit comprising:
- a plurality of power control lines each for controlling the open or closed state of one of the plurality of power control switches;

- a memory cell associated with said plurality of control lines; and
- power director means which in response to the mode of operation established by said mode controller selectively couples each of the plurality of power control 5 lines to said memory cell such that a signal is generated on the power control line that is dependent upon the state of the memory cell;
- said plurality of switches being controlled by the power switching circuit so that the power consumption of the computer system is controlled in response to the monitored activity of the computer system.

9. The power management system of claim 8 wherein the memory cell associated with each of the plurality of power control lines of the power switching circuit can be programmed by the CPU such that the status of the plurality of ¹⁵ power control switches in each of the plurality of modes of operation of the mode controller is programmable.

10. The computer system of claim 9 further comprising a polarity circuit coupled between each memory cell and each power control line wherein the polarity circuit selectively ²⁰ inverts the output of the memory cell associated with each power control line.

11. The power management system of claim 8 wherein the mode controller has at least three modes of operation;

- wherein each of the plurality of power control lines is ²⁵ associated with a bit stored in said memory cell;
- wherein said bit in said memory cell is alterable depending upon said mode; and
- wherein the power director means alters said bit to change control data on that power control line in each of the three modes of operation.

12. A power management system for use in a computer system comprising a power supply, a plurality of computer system circuits including a CPU circuit, an input/output circuit, and a memory circuit, a system bus which directly connects the CPU circuit with said input/output circuit and said memory circuit, and a plurality of power control switches which couple the power supply to provide operating power including bias voltages to transistors within said computer system circuits to the plurality of computer system circuits, wherein said power management system comprises:

- an activity monitor which monitors the activity of the computer system and generates an activity indicator signal reflective of said monitored activity;
- a mode controller responsive to the activity indicator signal of said activity monitor and having a plurality of modes of operation;

a power switching circuit comprising:

- a plurality of power control lines each for controlling 50 one of the plurality of power control switches;
- a memory cell associated with each of the plurality of control lines; and
- power director means which in response to the mode of operation of the mode controller selectively couples each of the plurality of power control lines to said memory cell associated with that power control line such that a signal is generated on the power control line that is dependent upon the state of the memory cell to which it is coupled; 60
- whereby the plurality of switches are controlled by the power switching circuit and the power consumption of the computer system is controlled in response to the activity of the computer system; and wherein

the mode controller has at least three modes of operation; 65 each of the plurality of power control lines is associated with a bit stored in said memory cell;

- said bit in said memory cell is alterable depending upon said mode; and
- the power director means alters said bit to change control data on that power control line in each of the three modes of operation;
- said power director means includes a multiplexer circuit, and the power switching circuit further comprises a polarity circuit coupled to the output of the multiplexer and to a plurality of the plurality of power control lines;

the polarity circuit comprises a plurality of polarity bits; each polarity bit has two states;

- in a first state of each polarity bit the polarity circuit inverts the signal on a corresponding power control line relative to the state of a corresponding associated memory cell; and
- wherein in the second state of each polarity bit the polarity circuit does not invert the signal on a corresponding power control line relative to the state of a corresponding associated memory cell.

13. A method for operating a computer system comprising a plurality of computer system circuits including a CPU circuit, a plurality of input/output circuits. and a memory circuit, a system bus which directly connects the CPU circuit with said plurality of input/output circuits and said memory circuit, a plurality of power control switches which selectively couple a power supply to the computer system circuits and having a plurality of functional power modes. wherein the method comprises the steps of:

- programming a first power control bit associated with each power control switch;
- programming a second power control bit associated with each power control switch;
- monitoring the activity of the computer system including identifying at least some of said plurality of activities as either active class or idle class activities and associating said at least some activities with an activity value having a magnitude component and algebraic sign component wherein said idle class activities have a sign opposite to said active class activities, accumulating an activity count as the sum of said activity values for each activity occurring during a predetermined monitoring period, and comparing the accumulated activity count with a threshold count and generating an indicator signal if the accumulated activity count has a predetermined algebraic relationship relative to the threshold count;
- switching the power mode of the computer system from a first mode to a second mode in response to said generated indicator signal indicating a first level of inactivity in the computer system;
- providing a signal to each of the plurality of power control switches dependent upon the state of the associated first power control bit in said first mode of the mode controller such that the state of that bit controls whether the switch is open or closed in said first mode; and
- providing a signal to each of the plurality of power control switches dependent upon the state of the associated second power control bit in said second mode of the mode controller such that the state of that bit controls whether the switch is open or closed in said second mode;
- whereby the power consumption of the computer system is controlled in response to the activity of the computer system.
- 14. The method of claim 13 further comprising the step of:

programming a polarity control bit;

and wherein the step of providing a signal to each of the plurality of power control switches dependent upon the state of the associated first power control bit in said first mode of the mode controller comprises the step of ⁵ selectively inverting the signal provided to each of the plurality of power control switches relative to the state of the associated power control bit depending upon the state of the polarity control bit;

and wherein the step of providing a signal to each of the ¹⁰ plurality of power control switches dependent upon the state of the associated second power control bit in said second mode of the mode controller comprises the step of selectively inverting the signal provided to each of the plurality of power control switches relative to the ¹⁵ state of the associated power control bit depending upon the state of the polarity control bit.

15. The method of claim 13 further comprising the steps of:

- programming a third power control bit associated with ²⁰ each of the plurality of power control switches;
- switching the power mode of the computer system from said second mode to a third mode in response to a second level of inactivity of the computer system;
- and providing a signal to each of the plurality of power control switches dependent upon the state of the associated third power control bit in said third mode of the computer system such that the state of that bit controls whether the switch is open or closed in third mode. 30

16. A method for operating a computer system comprising a plurality of computer system circuits including a CPU circuit, a plurality of input/output circuits, and a memory circuit, a system bus which directly connects the CPU circuit with said plurality of input/output circuits and said memory 35 circuit, a plurality of power control switches which selectively couple a power supply to the computer system circuits and having a plurality of functional power modes, wherein the method comprises the steps of:

- programming a first power control bit associated with 40 each power control switch;
- programming a second power control bit associated with each power control switch;
- monitoring the activity of the computer system and switching the power mode of the computer system from ⁴⁵ a first mode to a second mode in response to a first level of inactivity in the computer system;
- providing a signal to each of the plurality of power control switches dependent upon the state of the associated first power control bit in said first mode of the mode⁵⁰ controller such that the state of that bit controls whether the switch is open or closed in said first mode;
- providing a signal to each of the plurality of power control switches dependent upon the state of the associated second power control bit in said second mode of the mode controller such that the state of that bit controls whether the switch is open or closed in said second mode;
- programming a third power control bit associated with ₆₀ each of the plurality of power control switches;
- switching the power mode of the computer system from said second mode to a third mode in response to a second level of inactivity of the computer system;
- providing a signal to each of the plurality of power control 65 switches dependent upon the state of the associated third power control bit in said third mode of the

computer system such that the state of that bit controls whether the switch is open or closed in third mode; and programming a polarity control bit;

- said step of providing a signal to each of the plurality of power control switches dependent upon the state of the associated first power control bit in said first mode of the mode controller further comprises the step of selectively inverting the signal provided to each of the plurality of power control switches relative to the state of the associated power control bit depending upon the state of the polarity control bit;
- said step of providing a signal to each of the plurality of power control switches dependent upon the state of the associated second power control bit in said second mode of the mode controller comprises the step of selectively inverting the signal provided to each of the plurality of power control switches relative to the state of the associated power control bit depending upon the state of the polarity control bit; and
- said step of providing a signal to each of the plurality of power control switches dependent upon the state of the associated second power control bit in said third mode of the mode controller comprises the step of selectively inverting the signal provided to each of the plurality of power control switches relative to the state of the associated power control bit depending upon the state of the polarity control bit;
- whereby the power consumption of the computer system is controlled in response to the activity of the computer system.

17. In a power consumption management system for a computer system having a plurality of computer system devices receiving operating power from a common computer power supply, said computer system devices including a CPU device, an input/output device, and a memory device, and a single common system bus which directly connects the CPU device with the input/output device and the memory device, and wherein said computer system is adapted to perform a plurality of activities and has an activity level and a power consumption level as a result of performance of at least one of said plurality of activities; an activity monitor comprising:

- means for identifying each of said plurality of activities as either an active activity or an idle activity and for associating each of said plurality of activities with a predetermined activity value and with either a first arithmetic sign for activities identified as active activities or with a second arithmetic sign opposite to said first sign for activities identified as idle activities;
- an activity count accumulator for accumulating an activity count during a first predetermined time interval upon the occurrence of each of said plurality of activities including means for adding to a stored activity count, upon the occurrence of any one of said plurality of activities, a predetermined activity value associated with said particular activity;
- a comparator for comparing the accumulated stored activity count within said first predetermined time interval with a first threshold and for generating a first conserve power signal if the accumulated activity count is equal to the first threshold; and
- means for withholding said operating power from any one or more selected ones of said plurality of computer system devices in response to said first conserve power signal.

18. The activity monitor in claim 17, wherein said activity count accumulator further accumulates said activity count

during a second predetermined time interval longer than said first interval; wherein said comparator compares said count accumulated during said second interval with a second threshold and generates a second conserve power signal if the count accumulated during said second interval is equal to a second threshold; and wherein said means for withholding said operating power withholds operating power from any one or more selected ones of said plurality of computer system devices in response to said second conserve power is mitheld being greater than the number of devices from which said operating power is withheld in response to said first conserve signal.

19. The activity monitor in claim 18, wherein said activity count accumulator further accumulates said activity count 15 during a third predetermined time interval longer than said second interval; wherein said comparator compares said count accumulated during said third interval with a third threshold and generates a third conserve power signal if the count accumulated during said third interval is equal to a third threshold; and wherein said means for withholding said operating power withholds operating power from any one or more selected ones of said plurality of computer system devices in response to said third conserve power signal, a number of devices from which said power is withheld being 25 greater than the number of devices from which said operating power is withheld in response to said second conserve signal.

20. In a power consumption management system for a computer system having a plurality of computer system devices receiving operating power from a common computer power supply, said computer system devices including a CPU device, an input/output device, and a memory device, and a system bus which connects the CPU device with the input/output device and the memory device, and wherein said computer system is adapted to perform a plurality of activities and has an activity level and a power consumption level as a result of performance of at least one of said plurality of activities; a method for monitoring activity of said computer system comprising the steps of:

- ⁴⁰ identifying each of said plurality of activities as either an active activity or an idle activity and associating each of said plurality of activities with a predetermined activity value and with either a first arithmetic sign for activities identified as active activities or with a second arithmetic sign opposite to said first sign for activities identified as idle activities;
- accumulating an activity count during a first predetermined time interval upon the occurrence of each of said plurality of activities including adding to a stored 50 activity count, upon the occurrence of any one of said plurality of activities, a predetermined activity value associated with said particular activity;
- comparing the accumulated stored activity count within said first predetermined time interval with a first threshold and generating a first conserve power signal if the accumulated activity count is within a predetermined range of the first threshold; and
- withholding said operating power from any one or more selected ones of said plurality of computer system 60 devices in response to said first conserve power signal.

21. The activity monitor in claim 20, wherein step of accumulating an activity count further includes the step of accumulating said activity count during a second predetermined time interval longer than said first interval; and 65

said step of comparing further includes the step of comparing said count accumulated during said second interval with a second threshold and generating a second conserve power signal if the count accumulated during said second interval is within a predetermined range of a second threshold; and

said step of withholding said operating power includes the step of withholding operating power from any one or more selected ones of said plurality of computer system devices in response to said generation of said second conserve power signal, a number of devices from which said power is withheld in response to generation of said second conserve signal being greater than the number of devices from which said operating power is withheld in response to said first conserve signal.

22. The activity monitor in claim 21. wherein step of accumulating an activity count further includes the step of accumulating said activity count during a third predetermined time interval longer than said second interval;

- said step of comparing further includes the step of comparing said count accumulated during said third interval with a third threshold and generating a third conserve power signal if the count accumulated during said third interval is within a predetermined range of a third threshold; and
- said step of withholding said operating power includes the step of withholding operating power from any one or more selected ones of said plurality of computer system devices in response to said generation of said third conserve power signal. a number of devices from which said power is withheld in response to generation of said third conserve signal being greater than the number of devices from which said operating power is withheld in response to said second conserve signal.

23. In a computer system having a power management system and a plurality of computer system circuits including a CPU circuit, a plurality of input/output circuits, a memory circuit, a power supply for providing electrical power to operate at least one of said computer system circuits, a clock circuit for generating a clock signal, and a system bus which connects the CPU circuit with the input/output circuits, and wherein said computer system is adapted to perform a plurality of activities, a method for managing power use by said computer system comprising the steps of:

monitoring the activity of the computer system including the steps of:

- identifying each of said plurality of activities as either an active activity or an idle activity and associating each of said plurality of activities with a predetermined activity value and with either a first arithmetic sign for activities identified as active activities or with a second arithmetic sign opposite to said first sign for activities identified as idle activities;
- accumulating an activity count upon the occurrence of each of said plurality of activities including adding to a stored activity count, upon the occurrence of any one of said plurality of activities, a predetermined activity value associated with said particular activity; and
- comparing the accumulated stored activity count with a conserve threshold and for causing a conserve signal if the accumulated activity count has a predetermined algebraic relationship relative to the conserve threshold;
- controlling a power mode of operation in response to said conserve signal to select a mode of operation from among at least a first mode and a second mode; and
- controlling power consumption of said computer by transitioning operation of at least one of said computer

system circuits from an on state to a reduced power state in response to the conserve signal in which the power consumption of the computer is reduced relative to the power consumption in the on state.

24. The method in claim 23. wherein said step of controlling power consumption of said computer further comprises the step of controlling distribution of electrical power from said power supply to one of said computer system circuits.

25. The method in claim **24**, wherein said step of con- 10 trolling distribution of electrical power further comprises the steps of:

- associating at least some of said plurality of computer system circuits with a power control value for each of said on state and reduced state, wherein said on and ¹⁵ reduced power control value identify whether power is to be provided to or withheld from said computer system circuits during operation in said on state and said reduced state; and
- switchably controlling the connection of said power sup-²⁰ ply to said at least some of said computer system circuits based on said on and reduced power control values.

26. The method in claim 24, wherein said step of associating at least some of said plurality of computer system ²⁵ circuits with a power control value for each of said on state and said reduced state further comprises the steps of: providing a plurality of control bits for each of said on and reduced power control values in said memory; and associating each said control bit with a group of said devices. 30 wherein each said control bit can have a first logical state or a second logical state; and wherein said step of switchably controlling the connection of said power supply to said at least some of said computer system circuits based on said on and said reduced power control values further comprises the 35 step controlling the connection of said power supply to said devices based on the logic state of said associated control bit to close a switch and thereby connect said power supply to said device when only when said control bit has said first **4**0 logic state.

27. The method in claim 23, wherein said step of controlling power consumption of said computer further comprises the step of controlling the frequency of said clock signal distributed to one of said computer system circuits.

28. A computer system comprising a power management ⁴⁵ system and a plurality of computer system circuits including a processor circuit, at least one input/output circuit, a

memory circuit, and a bus which connects the processor circuit with the input/output circuit, said computer system adapted to perform a plurality of processing activities. wherein said power management system comprises:

- an activity monitor which monitors the processing activity of said computer system including:
 - identification logic identifying each of said plurality of activities as either an active class activity or an idle class activity and associating each of said plurality of activities with a predetermined activity value and with either a first arithmetic sign for activities identified as active class activities or with a second arithmetic sign opposite to said first sign for activities identified as idle class activities;
 - an activity count accumulator for accumulating an activity count upon the occurrence of each of said plurality of activities including and adder for adding to a previous activity count, upon the occurrence of any one of said plurality of activities, a predetermined activity value associated with said particular activity; and
 - a comparator coupled to said accumulator to receive said accumulated activity count and for comparing the accumulated activity count with a conserve threshold and for causing a conserve signal if the accumulated activity count has a predetermined algebraic relationship relative to the conserve threshold;
- a mode controller responsive to the activity monitor wherein the mode controller has a plurality of power modes of operation including a first mode and a second mode; and
- a control circuit coupled to said activity monitor and responsive to said activity monitor which in response to the conserve signal transitions said computer system from an on state to a reduced power consumption state in which the power consumption of the computer system is reduced relative to the power consumption in the on state by either: (i) removing a clock signal communicated to at least one of said computer system circuits, (ii) reducing the operating frequency of a clock signal communicated to at least one of said computer system circuits, (iii) reducing the electrical power delivered to at least one of said computer system circuits, or (iv) by a combination thereof.
