An apparatus and method for controlling an electronic press develops first and second sets of template data representing associated first and second template pages, respectively. Each set of template data includes master data representing fixed information to be printed and area data representing an area of a page in which variable information is to be printed. A database is developed having a number of entries, each of which represents variable printed information. An electronic press is responsive to sets of template data and the database to print the first and second template pages with selected variable printed information.

APPARATUS FOR CONTROLLING AN ELECTRONIC PRESS TO PRINT FIXED AND VARIABLE INFORMATION

TECHNICAL FIELD

The present invention relates generally to reproduction methods and systems, and more particularly to a method of and system for selectively reproducing images.

BACKGROUND ART

Most printing systems in use today utilize printing plates or cylinders which are engraved or photochemically processed to create an image thereon. Ink is then deposited on the plate or cylinder and the ink is thereafter transferred to a substrate, such as paper. In a conventional printing press, a number of pages are printed on a sheet of paper to form a signature which is then folded and assembled with other signatures. The assembled signatures are then bound, trimmed and finished by finishing apparatus to produce finished books, such as magazines, catalogs or any other printed and bound matter.

Often, there is a need to produce different versions of books and/or customized books within a single press run. For example, it may be desirable to produce a number of standard books together with a number of books having additional and/or different signatures or pages therein. Also, it may be necessary or desirable to provide customized information in the form of an address label, personalized information or the like on the inside or outside of finished books. In either case, conventional printing systems are not easily adaptable to produce books of these types.

A printing system which has the ability to produce differing book versions and/or books with customized information is disclosed in Riley U.S. Pat. No. 4,121,818, assigned to the assignee of the instant application. The printing system includes a number of packer boxes disposed adjacent a binding chain wherein each packer box stores a plurality of signatures. A control is included for controlling the packer boxes to selectively feed signatures onto chain spaces of the binding chain so that books of varying content can be produce. Customized information can be printed on the signatures by means of an ink jet printer which is selectively operated by the control. Other types of customization can be effectuated, such as by inserting or onserting cards or the like.

Other systems for producing customized books are disclosed in Abrams et al. U.S. Pat. No. 3,899,165, Wong et al. U.S. Pat. Nos. 4,500,083 and 4,674,052, Wong U.S. Pat. No. Re 32,690 and Berger et al. U.S. Pat. Nos. 4,768,766 and 4,789,147.

Image manipulating systems have been developed which permit gathering of images in an office or home environment. For example, conventional word processing programs, such as Microsoft® Words®, WordPerfect® and the like, permit a user to import images into a page and also allow a user to command which pages of a document to print. In addition, macros (i.e., a sequence of commands) can be assembled and executed within these programs which can allow printing of particular document pages in a certain order. Still further, most word processing programs have merge capability wherein a customized image is merged with other standardized information and printed or displayed. As one example, customized information in the form of addressee and address information may be merged with standardized return address information and printed on a series of envelopes.

A different image gathering capability provided by CAD (computer aided design) software, sometimes referred to as "layering," involves the creation and storage of a base page and one or more layer pages. A user can issue commands to display or print the base page and one or more of the layer pages simultaneously atop one another to achieve an effect similar to the overlay of transparencies so that a composite page appearance results.

While the foregoing image manipulating systems allow some image gathering capability, none is effective to assist in the rapid production of different book versions. Of course, CAD systems are primarily designed for line art and not text nor graphic images, and hence are of only limited use. Further, if one were to use word processing software to produce book versions it would be necessary to issue commands to separately print the pages of each book version just before such version is to be produced. That is, a user would have to create and store pages to be included in a first book version and then command the software to print as many copies of the first version as are needed. Thereafter, the user would have to recall the pages of the first version from memory, edit and store the pages to create pages to be included in a second book version and then command the system to print the required number of books of the second version. Similar steps would have to be undertaken for each other book version to be produced. Alternatively, the pages of the different book versions could be created and stored and thereafter printed together. In either event, where many book versions are to be produced, such a process would be quite time-consuming. In addition, image importation and merge routines provided as a part of word processing software are adapted for use on a sub-page basis only and hence are of only limited usefulness in the book production environment. Still further, data manipulated by word processing software are largely (if not entirely) in symbolic format. As a result, data to be displayed or printed must be first rasterized by a raster image processor (RIP), which utilizes complex and time-consuming computational routines which further increase production time to an economically impractical level.

Recently, new printing systems have been developed, called "demand printers," which are capable of high speed printing of images from electronic representations thereof. The demand printer produces high quality color images using a set of fusible toners in an electrophotographic process. More particularly, a web of paper is passed adjacent a series of drums, each of which has been electrostatically charged according to an image pattern for a particular color to be applied to the web. The charge is transferred to the paper and an oppositely charged toner of the proper color is brought into contact with the paper. The oppositely charged web and toner attract so that the toner is held on the paper as other colors are applied thereto. The toners and paper are thereafter heated to fuse the toners to the paper to produce the final image. The web is then cut into sheets (or "forms") and the forms are further processed as needed to produce a final product.

Unlike conventional presses which utilize engraved or photochemically prepared plates or cylinders, demand printers are capable of rapidly printing high quality images of differing content owing to the fact that the images are produced by an electrophotographic process. That is, instead of the need to replate and re-engrave a gravure cylinder when a different image is to be printed therewith, it is only necessary to change the charge applied to the drums of the printer in order to make such change. Thus, different images can be printed by the same printer without significant delays.

This advantage makes the demand printer desirable for use in certain production environments. However, applicants are currently unaware of any systems developed by others which utilize this advantage to produce differing book versions in an efficient manner.

SUMMARY OF THE INVENTION

In accordance with the present invention, an apparatus and method for controlling a display device such as an electronic press permits the display of fixed and variable information in a simple and effective manner.

More particularly, an apparatus and method for controlling an electronic press includes means for and the steps of developing first and second sets of template data representing associated first and second template pages, respectively, wherein each set of template data includes master data representing fixed information and area data representing an area of the page for variable information. A database is also developed having a number of entries each of which represents variable information. The electronic press is caused to print the first and second template pages with selected variable information.

Preferably, the sets of template data and the database are converted into commands for the display device specifying sequence and content of page production.

Also preferably, the sets of template data are separated into master files containing master data and intermediate variable page files having area data. Final variable page files are derived from the database and the intermediate variable page files, wherein the final variable page files include content data representing variable printed information. The commands may be developed from the master page files and the final variable page files.

According to a further aspect of the present invention, an apparatus for controlling an electronic press wherein the press includes a controller responsive to press commands includes first means for developing a template file defining pages to be printed with fixed information common to all of the associated pages and variable information unique to each page, as well as means for assembling a database having entries therein each representing variable information to be printed. Second means are responsive to the first developing means for developing a master page file from the template file wherein the master page file defines the fixed information. Means are responsive to the assembling means and the first developing means for converting the template file and the database into press commands specifying sequence and content of page production by the press.

In accordance with yet another aspect of the present invention, an apparatus for controlling an electronic press wherein the press includes a controller responsive to press commands includes first means for developing a plurality of template files each defining associated pages to be printed with and having first data defining fixed information common to all of the associated pages and variable information unique to each associated page. At least one of the template files further includes second data defining a particular area in each associated page for the printing of variable information therein and third data identifying at least one of the database entries. Means are provided for assembling a database having entries therein each representing variable information to be printed. Second means are responsive to the first developing means for developing a master page file from the template file wherein the master page file includes data defining the fixed information only. Means are responsive to the assembling means and the first developing means

for converting the template files and the database into press commands specifying sequence and content of page production by the press.

The apparatus and method of the present invention permit high speed printing of quality images and are particularly suited to the production of differing book versions and/or books with customized and/or personalized information within a single production run.

Other features and advantages are inherent in the apparatus claimed and disclosed or will become apparent to those skilled in the art from the following detailed description in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram illustrating a prior art method of producing books;

FIG. 2 is a block diagram of a method of producing books according to the present invention;

FIG. 3 is a block diagram illustrating an exemplary system for implementing the method of the present invention illustrated in FIG. 2;

FIG. 4 is a block diagram illustrating one of the demand printing systems of FIG. 3 in greater detail;

FIG. 5 is a generalized diagram of the steps implemented by the method of the present invention;

FIGS. 6a and 6b are elevational views of a sample book that may be produced by the present invention;

FIGS. 7a, 7b and 8a, 8b are elevational views of other sample books that may be produced by the present invention;

FIG. 9 is a flowchart illustrating programming that may be executed by a user on a personal computer to create the template files 105 of FIG. 5;

FIGS. 10a-10f, when joined along similarly-lettered lines, together represent programming executed by the control unit 52 of FIG. 3 to implement the present invention;

FIGS. 11a-11c, when joined along the similarly-lettered lines, together represent programming executed by the control unit 52 of FIG. 3 to impose pages to be printed by one of the demand printing systems of FIG. 3; and

FIG. 12 illustrates programming executed by the control unit of 52 of FIG. 3 to convert page files into bitmap format.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. 1 illustrates a prior art method of producing books, for example as shown in the above-identified Riley et al. '818 patent identified above. During a publishing step 20, the contents of one or more book versions are determined. Each version may comprise, for example, a set of standard or common pages. In addition, some of the versions may include one or more additional pages or other customized information. Thereafter, during a preliminary step 22, color correction of color images is undertaken together with undercolor removal and screening for halftone images. During a prepress step 24, page imposition is effected and printing cylinders or plates are prepared. The plates or cylinders are then used during a printing step 26 to prepare signatures which are loaded into packer boxes (not shown). As noted in the Riley et al. '818 patent identified above, the signatures are then selectively collected on a gathering chain (not shown) during a book assembly step 28 and the gathered signatures are bound and trimmed to create the books. The books are thereafter distributed during a step 30 to users

via one or more distribution systems, for example, the U.S. Postal Service.

As should be evident from the foregoing, customization occurs during the book assembly step **28**, inasmuch as the choice of particular signatures to be included in a book is made at that time. In addition, customized information can be printed onto selected signatures using an ink jet printer disposed adjacent the gathering chain. Thus, for example, addressee information can be printed by the ink jet printer on assembled books so that preprinted addressee labels need not be used. Other types of customization can be effected at this time, for example, by inserting or onserting cards into or onto a stack of collected signatures, affixing a specialized or customized cover on a gathered stack of signatures, or the like. Customization at this point in the production process is simpler and less expensive than, for example, separately printing each book version with customized information.

FIG. 2 illustrates a block diagram of a method **40** according to the present invention which may be used in place of the method of FIG. 1 to produce books. The method **40** includes a step **42** which utilizes the output of publishing and preliminary steps **36**, **38** and produces books for distribution according to the step **30** of FIG. 1. The step **42** creates one or more master and variable page files in, for example, a page description language (PDL) such as PostScript® (PostScript® is a trademark of Adobe Systems, Inc. for its page description language) representing pages to be produced. In addition, as noted in greater detail hereinafter, a press command file is developed which specifies the manner in which data contained within the master and variable page files are to be merged to produce printed pages. The format of the press command file is specified by Barco Graphics of Gent, Belgium and is particularly suited for control of a DCP-1 digital color press manufactured by Xeikon of Mortsel, Belgium. It should be noted that the apparatus and method of the present invention are not limited to use with a particular type of demand printer or a particular system for controlling such a printer, inasmuch as the invention can be adapted for use with any type of printer or control whether located locally or remotely.

The master and variable page files and the press command file are converted by a collator and raster image processor (RIP) into bitmaps which may be stored in a memory. The stored bitmaps are used to control one or more demand printers and/or any other type of display device, such as a laser printer, a CRT, an LCD display or the like so that the device displays pages having fixed and variable information thereon. Alternatively, the master and variable page files may be premerged to create a plurality of combined files each representing a page to be reproduced with master and variable information. The combined files can be then sent to any type of printer or other display device, whether local or remote. Also, the combined files can be converted to a suitable format (e.g., Acrobat® PDF format) and transmitted to a remote location using a facsimile machine, e-mail or other transmission medium if desired.

During a finishing step, the assembled books are bound and trimmed and, if desired, further customization can be effected.

FIG. 3 illustrates a system **50** which implements the steps **36**, **38** and **42** in the method **40** of FIG. 2. A control unit **52**, which may be implemented by a personal computer or another type of computer, includes a memory **53** and stores therein data representing images to be printed. As noted in greater detail hereinafter, the data may be specified by a publisher using a personal computer **54** or any other type of

computer and may comprise one or more template files specifying pages to be produced with master or fixed printed information (i.e., printed information which does not vary from book to book of the same version) and variable printed information (which typically varies from book to book). The variable information may be stored in a database created by the publisher and the template file(s) specify the locations on particular pages for variable information stored in the database as noted in greater detail hereinafter.

If desired, image data may be obtained from any other type of device or devices, such as a scanner which scans input copy, data supplied over a network or any other source. The control unit **52** is further responsive to control and makeready files and causes one or more demand printing systems **62** to print desired pages. While three demand printing systems **62a–62c** are illustrated in FIG. 3, it should be understood that the control unit **52** may operate a different number of demand printing systems, as desired. Also, the control unit **52** may operate a fax machine **64** and/or may communicate with other remote devices to send properly converted combined files, as desired and as noted above. The combined files may be printed or may alternatively be reproducible in a different medium and/or may comprise a non-static image or other information, i.e., movies or audio.

The pages printed by the demand printing system **62** may be supplied to a finishing apparatus **66** which includes various auxiliary production devices and device interfaces for assembling the pages to produce finished books which are ready for distribution. The finishing apparatus **66** may include one or more gathering devices **70** for gathering printed pages into books, one or more ink jet printers **72** for printing additional customized information, such as addressee information, on each book, one or more label printers **74** for printing address labels and/or other control devices **76**. In addition, one or more detectors **78** may be provided to sense when a defective book is produced. The control unit **52** may be responsive to the output of the detector **78** to reorder a defective book at an appropriate point in the production sequence thereof so that advantage can be taken of postal discounts, if possible.

FIG. 4 illustrates the demand print system **62a** of FIG. 3 in greater detail, it being understood that the systems **62b** and **62c** are identical thereto. The system **62a** includes a print system **79** having a press controller **80**, a collator **81** and a raster image processor (RIP) **82** which are operable in response to press commands generated by the control unit **52**. A collator is an electronic device for storing raster image processor files (i.e., bitmap files) and delivering selected files to a digital press in real time, such that the digital press can run at full speed while processing and printing unique page data for each book produced on the press. The RIP **82** converts the page files to bitmap format or any other format, such as a symbolic printer control language. The collator **81** includes memory in the form of mass storage drives and physical memory and collates the bitmap page files. If desired, the collator **81** and/or RIP **82** may comprise a part of the press controller **80**. The controller **80** instructs the collator **81** to send page files to the demand printer **84**. The print system **79** may comprise the PrintStreamer system, manufactured and marketed by Barco Graphics of Belgium, while the demand printer **84** may comprise the Xeikon DCP-1 digital color press noted above. It should be noted that a different print system and/or demand printer may alternatively be used, such as the Indigo printer manufactured by Indigo NV, of Maastricht, Netherlands if desired.

FIG. 5 illustrates in diagrammatic generalized form the method of the present invention. For the purpose of explain-

ing the present invention, as a first example, it will be assumed that the demand print system **62a** will be operated to produce three four-page books in the form of a brochure in duplex format. That is, as seen in FIGS. **6a** and **6b**, a first sheet of paper **100** is to be printed on a first side **100a** with printed pages **P1**, **P4** while a second side **100b** of the sheet **100** is to be printed with pages **P2**, **P3**. In addition, pages **P1–P4** are to be imposed such that the page **P1** is placed on a right-hand portion **100a-r** of the side **100a** while the page **P4** is placed on a left-hand portion **100a-l** of the side **100a**. Further, the page **P2** is to be placed on a left-hand portion **100b-l** of the side **100b** while the page **P3** is to be placed on a right-hand portion **100b-r** of the side **100b**. In this fashion, when the sheet of paper **100** is folded along a fold line **102** with the pages **P1** and **P4** on the outside, the pages **P1–P4** will appear in sequence. Because each book to be produced in this example comprises only a single sheet of folded paper, the imposition process need not take into account shingling or bottling effects, although it should be noted that such effects may have to be taken into account when more than one sheet of paper is assembled with other sheets of paper to produce a book and/or when more than two pages are to be printed on a single side of a sheet of paper and thereafter assembled with other pages to create a book.

In addition to the foregoing, in the first example, assume that the three books to be produced include variable and fixed information on the first and last pages of each book and fixed information only on the remaining pages. For example, the page **P1** may include variable information in the form of a personalized message, a variable image, or the like in an area **110** whereas the page **P4** may include other variable information in an area **112**, for example, postal information for mailing the brochure to an addressee. Corresponding front and back pages of the remaining books may include different variable information. The remaining printed information on pages **P1–P4** is identical to the printed information on corresponding pages of the other two books.

It should be noted that the present invention is not limited to production of books of the same "version" (i.e., books having the same master information). For example, the book versions of FIGS. **7a**, **7b** and **8a**, **8b** may be produced together with the book version of FIG. **6a** and **6b** in the same production run or job. The book version example of FIGS. **7a** and **7b** includes pages **P5–P8** to be reproduced a number of times to produce individual books. The book version of FIGS. **7a** and **7b** is identical to of the book version of FIGS. **6a** and **6b** except that an additional area **113** is provided on the page **P5** for placement of variable information, in addition to the areas **110** and **112**. Because of the addition of the area **113**, the remaining master information appearing in an area **114** differs from master information appearing in an area **116** of the page **P1** of FIG. **6a**.

The book version example of FIGS. **8a** and **7a** differs from the book version examples of FIGS. **6a**, **6b** and **7a**, **7b** not only in terms of content of master and variable information, but also number of pages and page size. Specifically, eight pages **P9–P16** are to be printed wherein the pages **P9**, **P12**, **P13** and **P16** are to be printed in a first side **117a** of a sheet of paper **118** and the remaining pages **P10**, **P11**, **P14** and **P15** are to be printed on a second side **117b** of the sheet **118**. In addition, the pages **P11–P14** are printed upside down relative to the remaining pages so that, when the sheet **118** is folded first along a fold line **119a** and then along a fold line **119b**, the resulting pages **P9–P16** appear in order. Thereafter, the folded sheet **118** is trimmed to separate the pages **P9–P16**. As should be evident, the pages **P9–P16** are one-half the size of the pages **P1–P8**, and further include different master and variable information thereon.

It should be noted that books assembled from multiple printed "forms" (defined in greater detail hereinafter) may alternatively or in addition be produced by the present invention, if desired.

Referring again to FIG. **5**, one or more template files **106** are developed by a publisher specifying the content (including appearance) of fixed information and the positioning of all information (i.e., fixed and variable) on the different books or book versions. A database **108** is also developed by the publisher using the personal computer **54** specifying the content of variable information to be placed in variable information areas, for example, the areas **110**, **112** on the pages **P1**, **P4**, respectively, of FIGS. **6a** and **6b**. The database **108** further includes control information, as noted in greater detail hereinafter.

The template files **106** include data specifying the position and content of fixed information on the pages to be printed. Specifically, the template files **106** define template pages wherein each template page includes data representing any fixed information to be reproduced on corresponding pages of the books or book versions and area data representing any area(s) on the corresponding pages where variable information is to be reproduced. The template files are duplicated to create working files. One set of working files is stripped of all area data relating to placement of variable information to create stripped master page files **120** defining template pages having only fixed information thereon. The stripped master page files are then converted into PDL master page files **122** expressed in a page description language, such as PostScript®. An optional imposition process may then convert the PDL master page files **122** into imposed master page files **124** each representing a side of a piece of paper to be printed with at least one, and, likely, two or more template pages having fixed information only thereon. Such a template page may be identical to that shown in FIG. **6a** except that the areas **110** and **112** are removed therefrom.

A further set of working files is stripped of all fixed information to create stripped variable page files **126** defining template pages having fixed information removed therefrom and further having the area data defining the areas **110**, **112**. The data representing template pages having variable information thereon are expanded into a set of intermediate page files. In the example of FIGS. **6a** and **6b** where three books are to be printed, two intermediate page files **130**, **132** are thus produced. The file **130** includes a file portion **P1-a** defining the position of variable information to be produced on the page **P1** for the first book. Two other file portions **P1-b** and **P1-c** define the position of variable information to be produced on the front pages of the remaining two books. In like fashion, file portions **P4-a**, **P4-b** and **P4-c** represent the position of variable information to be reproduced on the last pages of the three books. At this point, data are also contained in each of the files **130**, **132** identifying the entries in the database **108** to be placed in the areas **110**, **112** during printing.

The files **130**, **132** are then converted into variable page files **134**, **136**. The files **134**, **136** are identical to the files **130**, **132**, respectively, except that the data in each file identifying entries in the database are replaced by the actual data stored at such entries.

The files **134**, **136** are converted into files **137**, **138** in a PDL format, for example, PostScript®. An optional imposition process may convert the PDL files into imposed final variable page files **139**.

The print system **79** operates in response to the press commands in a press command file **140** and merges the page

files 122, 137 and 138 (if no imposition is to be effected) or merges the page files 124 and 139 (if the pages are imposed) to create the finished books or book versions.

FIG. 9 illustrates a flow chart of programming executed by the personal computer 54 for creating the template file(s) 106 of FIG. 5. The programming may be written as an extension of Quark Xpress®, a page make-up program distributed by Quark, Inc. of Denver, Colo. The Quark Xpress® program may be adapted for operation on the Apple® Macintosh® operating system or any other operating system, such as the Microsoft Windows® operating system. Alternatively, a different page make-up program may be used, if desired.

During the make-up process for a book consisting of one or more pages, a template file is created for each book version to be produced, or, where a book is to include two or more parts (referred to as "sections" hereinafter) a template file may be created for each section. At a block 150 a user may select an area of a page for reproduction of variable information therein, at which point a line object, a text object or an image object may be selected. A block 152 then checks to determine which type of object has been selected. If a text object has been selected, indicating that variable text is to be inserted at a point defined by the current cursor position on the computer display, the name of the appropriate field in the database 108 is inserted into the template file at the insertion point defined by the current cursor position. If the user wishes to designate more areas for variable information (block 156) control returns to the block 150 to await selection by the user. If the user then selects an image object, a box is defined by the user to contain an image at a desired location on a selected page. Control from the block 152 thereafter passes to a block 158 which inserts a dummy picture file and an indication of the proper database field name in the template file for the page at the location

in the upper left corner of the image box. Control thereafter proceeds to the block 156.

If the block 152 determines that a line object has been selected, control returns directly to the block 150, inasmuch as variable information cannot be entered into a line object.

At any point during the page make-up process, other functional aspects of the Quark Xpress® program may be invoked as necessary to produce finished pages.

Once the user determines that no more variable data is to be inserted into the document (block 156), the resulting page template files(s) are stored on a storage medium, such as an optical disc or other storage device, and/or the file(s) are downloaded together with the database to the control unit 52.

The database 108 is assembled by creating an ASCII file having a plurality of records wherein each record includes one or more fields entered into the database in tab-delimited format (i.e., the fields are separated from one another in each record by tab keystrokes and the records are separated from one another by line returns) and wherein the fields are arranged under field names of a header. Each field may include text to be reproduced on a page or a name of an image file stored in the memory 53 and defining an image to be reproduced on a page.

In addition to the foregoing data, the database 108 may include an optional field designating the number of copies of each book to be produced, an optional townsort image field, a version identification field indicating book version number if multiple book versions are to be produced, an optional distribution list field, control data and the like.

A sample database is set out below having a header consisting of twelve fields (i.e., "version," "addressline1," "addressline2," etc.) and a number of records, nine of which are shown, each having twelve fields:

Version	Addressline1	Addressline2	Addressline3	Addressline4	Addressline5	Price1	Image1	Price2	Copies	Barcode	Townsort
01	William Doe	123 Elm	Chicago	Illinois	606248923	\$22.95	Shoes	\$21.95	1	!606248923!	
03	Hugh Jorgensen	56 Maple	Chicago	Illinois	606248923	\$21.95	Shirt	\$20.95	1	!606248923!	
02	Jay P. Morgan	1313 Park	Chicago	Illinois	606248924	\$24.95	Pants	\$22.95	1	!606248924!	■
02	Joe Louis	819 Elm	LaGrange	Illinois	605251093	\$19.95	Pants	\$18.95	1	!605251093!	
03	John Smith	926 Cossit	LaGrange	Illinois	605251093	\$19.95	Shoes	\$15.25	1	!605251093!	
01	Len Johnson	882 Monroe	LaGrange	Illinois	605251093	\$19.95	Shoes	\$17.25	1	!605251093!	
02	Janet Cizmar	916 Monroe	LaGrange	Illinois	605251094	\$24.95	Pants	\$21.95	1	!605251094!	■
03	Jay Schroeder	88 W. 77th	Brookfield	Illinois	605241391	\$21.95	Shirt	\$19.95	1	!605241391!	
03	John Doe	129 Madison	Brookfield	Illinois	605241391	\$22.95	Shirt	\$19.95	1	!605241391!	■

indicated by the current cursor position. The user will thereafter see the dummy picture file at the insertion point on the display of the computer 54 when the page is viewed. The dummy picture file will display an indication of which database field will be used for insertion on the respective pages.

Following the block 158, a block 160 prompts the user to enter an indication of whether the image object is to be displayed in one of two display formats. If the image is to be displayed in other than the original size thereof, a block 162 sets a subtitle defined for the image to "fit," indicating that the image is to be scaled to fit the box. If the image is to be displayed in the original size thereof, a block 163 prompts a user to select a position for the image at a particular location in the box defined therefor, such as the upper left-hand corner, the lower right-hand corner, or the like. If the user does not select a position, the image is placed

In the example of FIGS. 6a and 6b, the field names ADDRESSLINE1 through ADDRESSLINE5, BARCODE and TOWNSORT may appear in the area 112 and one or more of the field names PRICE1, IMAGE1 AND PRICE2 may appear in the area 110. Inasmuch as only a single version is to be produced in the example of FIGS. 6a and 6b, the VERSION field would not be used. The COPIES field may be used as a control code to select the number of book copies to be produced.

Once the template file(s) 106 and the database 108 are assembled, the programming of FIGS. 10a-10f may be executed by the control unit 52 to create the master page files 122 or 124, the final variable page files 137, 138 or 139, and the press command file 140. Referring first to FIG. 10a, a block 170 prompts a user to select a template file 106 and a block 172 opens the database 108. A block 174 then reads and stores in a list the database field names for later

reference and a block 176 prompts a user to enter information indicating a section number and whether pages are to be printed in simplex (i.e., single-sided) or duplex (i.e., double-sided) format. The section number identifies the order in which multiple sections are to be processed for a particular book. The user may also be prompted to enter a selective processing code identifying a particular book version to process if multiple versions are to be produced during a single press run.

Following the block 176, a block 177 begins the process of stripping variable information from the template file opened by the block 170 to obtain the stripped master file 120 of FIG. 5. The block 177 selects a first page for processing and a block 178 checks to determine whether there are any images in the template file and, if images are located, a block 180 selects a first image. A block 182 identifies the file name for the image and a block 184 checks the field list to determine whether the file name is included therein. If the file name for the image is included in the field list, then the image comprises variable information and a block 186 deletes the image block. Otherwise, the block 186 is skipped and a block 188 checks to determine whether all images have been processed. If not, a block 190 selects a next image and control returns to the blocks 182–188. Control remains with such blocks until the block 188 determines that all images have been processed and control then passes to a block 192. Control also passes to the block 192 from the block 178 should the latter determine that there are no images in the template file.

The block 192 determines whether any text boxes are present in the open template file. If at least one text box is present, a block 194 selects and parses a first text box and a block 196 checks to determine whether the text box includes at least one of the field names of the database 108. If so, then it has been determined that the text box includes variable information and a block 198 deletes the text box. Otherwise, the block 198 is skipped and a block 200 checks to determine whether all text boxes in the template file have been processed. If not, a block 202 selects and parses the next text box in the template file and control returns to the blocks 196–200. Control remains with such blocks until all text boxes have been processed, whereupon a block 203 determines whether all pages have been processed. If not, a block 204 selects a next page and control returns to the block 178. Otherwise, a block 205 saves the resulting file as the stripped master file.

Control also bypasses the blocks 194–202 and proceeds directly from the block 192 to the block 203 if there are no text boxes in the open template file.

Following the block 205, a block 206, FIG. 10b, converts the stripped master file into the PDL master page file 122 of FIG. 5. At the same time, an initialization (or INI) file is created in ASCII code according to the following format:

```
name: [file path\name]
psx: [dimension]
psy: [dimension]
ssx: [dimension]
ssy: [dimension]
posx: [dimension]
posy: [dimension]
duplex: [zero or one]
orientation: [zero or one]
output: [filename]
copies: [number]
```

Where “psx” and “psy” refer to finished page sizes in x and y directions, “ssx” and “ssy” refer to cut sheet size in x and y directions, “posx” and “posy” refer to offsets in x and y directions specifying placement of each page on a cut sheet, “duplex” refers to single or two-sided printing, “orientation” refers to portrait or landscape printing, “output” refers to the name of the output file and “copies” refers to the number of copies to be printed. A sample INI file which specifies parameters for printing of a file called MYJOB.PS is as follows:

```
Name: C:\jobs\myjob.ps
psx: 8000
psy: 11000
ssx: 11500
ssy: 9000
posx: 150
posy: 150
duplex: 1
orientation: 1
output: myjob.ps
copies: 1
```

In the foregoing example, one copy of the file MYJOB.PS is to be printed in duplex and portrait formats at an offset of 0.15×0.15 inches from a corner of a finished sheet of paper 8×11 inches cut from a sheet originally having dimensions of 9×11.5 inches.

Following the block 206, a block 208 then reopens the same template file originally opened by the block 170 to begin the process of creating the stripped variable page files 126 of FIG. 5. A block 209 selects a first page and a block 210 checks to determine whether there are any images in the file and, if so, a block 212 selects a first image for consideration. A block 214 identifies the file name for the image and if a block 216 determines that the file name is not in the field list, then the image comprises fixed information (i.e., image will be the same in all of the books of a given version) and hence the image box is deleted by a block 218.

On the other hand, if the file name for the image is in the database field list, then the image is of the variable type (i.e., the image changes with the books of a given book version), and hence a block 220 identifies and saves the image box location on the page, the characteristics of the image box, such as the size, skew, background color and subtype and the like and further saves the field name of the image from the database 108. Also, a counter in the memory 53 which tracks the number of variable image boxes on the page is incremented.

Control from the blocks 218 and 220 passes to a block 222 which checks to determine whether all images have been processed. If not, a block 224 selects a next image and control returns to the blocks 214–222. Otherwise, control proceeds to a block 226 which begins the process of selecting and identifying text boxes. If there are text boxes present in the template file, a block 228 selects and parses a first text box and a block 230 checks the parsed text box to determine whether it includes one or more field names from the database. If not, then it has been determined that the text box includes only fixed information, and hence a block 232 deletes the text box. Otherwise, a block 234 stores the text box location, the insertion points in the text box at which variable information is to be printed and the characteristics of the text box and the field names of the database 108 identified in such text box in the memory 53. In addition, a variable text box counter is incremented representing the number of text boxes appearing on each page.

Control from the blocks **232** and **234** proceeds to a block **236** which checks to determine whether all text boxes have been processed. If not, a block **238** selects and parses the next text box and control returns to the blocks **230–236**. Once all text boxes have been processed, or if the block **226** determines that there are no text boxes in the template file, a block **239** determines whether all pages have been processed and, if not, a block **240** selects the next page and control returns to the block **210**. Otherwise, control passes to a block **241**, FIG. **10c**, which saves the resulting file as the stripped variable file **126** of FIG. **5**.

Control also passes to the block **239** from the block **226** if there are no text boxes found.

A block **242** then creates a working copy of the stripped variable file **126** and a first page having variable data thereon is selected and data representing the remaining pages in the file are deleted by a block **244**. A block **246** then deletes the data representing remaining pages in the file. In the example of FIGS. **6a** and **6b**, the block **244** creates a file defining the front page of a book with all fixed information deleted therefrom and an area reserved for variable information.

Following the block **244**, a block **246** selects a first record in the database **108** and a block **248** reads the record. An optional block **250** checks to determine whether a selective processing code has been entered by the user indicating that the page is to undergo selective page processing. As noted above, the apparatus and method of the present invention may be utilized to produce not only books of a single version (i.e., where corresponding pages differ only in terms of the variable information stored in the database) but also books of different versions. In the latter case, the books of different versions have different fixed and variable information. The fixed and/or variable information may vary in terms of content or appearance (i.e., style, location, rotation, position, etc.) or both in different versions.

If the block **250** determines that selective page processing is to be undertaken, then a block **252** checks to determine whether the database record read by the block **248** is utilized on the page currently under consideration. If this is not the case, a block **253** checks to determine whether the record currently under consideration is the last in the database. If so, control passes to a block **294** of FIG. **10e**. Otherwise, a block **254** selects a next record in the database **108** and control returns to the block **248** where the next database record is read.

If the block **250** determines that selective page processing is not to be undertaken, or if the block **252** determines that the record read by the block **248** is used in the page currently under consideration, a block **256** duplicates the data representing the page remaining after execution by the block **244** to initiate development of one of the files **130** or **132**. In the first pass through the program of FIG. **10c**, and in connection with the example of FIGS. **6a** and **6b**, the block **256** creates the file **130** and develops page data representing a first version of the page **P1-a** and adds further variable information to such page data during immediately succeeding passes through the program. Thereafter, data representing the remaining pages **P1-b**, **P1-c** and **P4-a** through **P4-c** are created and variable information is added to such pages serially during subsequent passes.

A block **258** checks to determine whether there are any image boxes on the page and, if so, a block **260** selects a first image box. A block **262** then inserts the image identified by the database field into the image box. A block **264**, FIG. **10d**, checks the subname to determine whether the block **162** of FIG. **9** has indicated that the image should be sized to fit the image box. If this is true, a block **266** performs the scaling.

Otherwise, a block **268** positions the image in the image box at the position specified by the user and a block **270** checks to determine whether all image boxes have been processed. Control also passes from the block **266** directly to the block **270**, thereby skipping the block **268**. If not all image boxes have been processed, a block **272** selects a next image box on the page and control returns to the blocks **262–270** so that remaining image boxes are serially processed.

Once the block **270** determines that all image boxes have been processed, or immediately following the block **258** of FIG. **10c** if no image boxes are found on the page, a block **274** checks to determine whether there are any text boxes on the page and, if so, a pair of blocks **276**, **278** select a first text box and a first insertion point in such box. Blocks **280**, **282** and **284** serially insert text data stored in the database **108** at the appropriate insertion points in the text box. Once all of the variable text data have been inserted into the text box, a block **286** recomposes all text in the text box so that the text obtains a neat finished appearance. The recomposition process is automatically undertaken by the Quark Xpress® program once the variable information is inserted into each text box. The recomposition process is responsive to the user commands as applied to the template file page, such as left, right, center, or full justification, hyphenation and the like. Following the block **286**, a block **288**, FIG. **10e**, checks to determine whether there are remaining text boxes to be processed on the page and, if so, a block **290** selects the next text box on the page and control returns to the blocks **278–288** to insert text information into such text boxes.

Once the block **288** determines that all text boxes for the page have been processed, the programming required to produce one of the pages of the file **134** of FIG. **5** having variable information only thereon is complete. A block **292** then determines whether all records in the database have been considered for inclusion in additional variable pages of the file **134** to be produced. If not all records have been considered, control returns to the block **254**, FIG. **10c**, where the next database record is identified and read. On the other hand, if all pages of the file **134** have been produced by considering all records in the database **108**, a block **294** converts the file data into PostScript® or another PDL format to create the variable page file **137** of FIG. **5**. Also, an INI file is created as before, except that the “duplex” parameter is set to command simplex printing only. If necessary or desirable, should the press run length exceed a certain limit, the programming may be modified to create more than one variable page file for each variable page of the template file.

Following the block **294**, a block **296** checks to determine whether there are other variable pages in the stripped variable page file to be processed. If this is true, a block **298** produces a new copy of the stripped variable file, selects the next variable page therein and deletes remaining pages therefrom. Control then returns to the block **246** of FIG. **10c**. In the example of FIGS. **6a** and **6b**, the back page **P4** and the corresponding pages of the remaining books are now selected for processing. In the fashion noted above, a file representing the variable portions of such pages is produced by developing the file representing the pages **P4-a** through **P4-c** and inserting the database information into such file to obtain the variable page file **136** and the PDL version **138**.

Following generation of the variable page files **134**, **136**, and **137**, **138** control passes to a block **300** which checks to determine whether a press command file has already been created. If not, a file is created by a block **302** having placeholder comments indicating where in the press command file individual press commands are to be placed for

15

each book to be produced. The press command file may also include data from one or more fields of the database **108** identifying an intended recipient of each book to be produced to assist in reproducing books found to be defective or to produce sample books. At this point, the press command file for the example of FIGS. **6a** and **6b** may be as follows (using data from the sample database set out above):

```
;RECORD1
:WILLIAM DOE:606248923
;ENDRECORD
;RECORD2
;HUGH JORGENSEN:606248923
;END RECORD
;RECORD3
;JAY P. MORGAN:606248924
;END RECORD
```

Following the block **300** (if the press command file already exists) or the block **302** a block **304** selects the first database record and a corresponding first record in the press command file. A block **306** then checks to determine whether the template file currently being processed includes the selected database record. If not, a block **308** determines whether all pages have been processed, and if this is not the case, the next record in the database **108** and a corresponding record in the press command file are selected. Control then returns to the block **306**. If the block **306** ascertains that the template file includes the selected record, a block **312** inserts an indication of the section number in the press command file at an appropriate point if the section number is not already present. If the section number is present already, the press command identified by the section number entered by the user at the block **176** is identified to be overwritten at a later point. The press command file now appears as follows for the example of FIGS. **6a** and **6b**:

```
;RECORD1
:WILLIAM DOE:606248923
;SECTION 1
;ENDSECTION
;ENDRECORD
;RECORD2
:HUGH JORGENSEN:6062488923
;SECTION 1
;ENDSECTION
;END RECORD
;RECORD3
;JAY P. MORGAN:606248924
;SECTION 1
;END SECTION
;END RECORD
```

Following the block **312**, a block **314**, FIG. **10f**, selects a first page of the section and a block **316** checks the state of a flag stored in the memory **53** to determine whether a simplex or duplex job has been requested. If a simplex job has been requested, the file name and page number of the master page file and, if variable information is to appear on the page, the file name and page number of the variable page file for the selected page are stored as a single set pair in the memory **53** by a block **318**. The determination of whether variable information is to appear on the selected page is accomplished by summing the contents of the variable image box counter and the variable text box counter as incremented by the blocks **220** and **234** of FIG. **10b**.

A block **320** checks to determine whether all pages have been processed and, if not, the next page is selected by a

16

block **322** and control returns to the block **316** for processing of such page. If all pages have been processed, control passes to a block **324** which determines whether all database and press command records have been processed. Control also passes to the block **324** if the block **308** determines that all pages have been processed. If not all records have been processed at this point, control returns to the block **310** where the next records in the database and press command file are selected.

If the block **324** determines that all records for the current section have been processed, a block **326** determines whether another section is to be processed and, if so, control returns to the block **170** of FIG. **10a**. If there is not another section to be processed, the press command file has been fully assembled, and hence the process terminates.

If the block **316** determines that a duplex job is to be effected, control passes to a block **328** which stores in the memory **53** a command identifying the file names and page numbers of the master page file (as well as corresponding information relative to variable page files, if variable information is to appear) as two-set pairs. Control from the block **328** then passes to the block **320** described above.

The result of the programming of FIGS. **10a-10f** is a press command file having a sequence of press commands which cause printing of pages in a desired order. In the example of FIGS. **6a** and **6b**, the press command file would read as follows:

```
BOOK A
;RECORD1
:WILLIAM DOE:606248923
;SECTION 1
"file.m"1@"file.1"1|"file.m"2
"file.m"3|"file.m"4@"file.4"1
ENDSECTION
ENDRECORD
;RECORD2
;HUGH JORGENSEN:606248923
;SECTION 1
"file.m"1@"file.1"2|"file.m"2
"file.m"3|"file.m"4@"file.4"2
;ENDSECTION
;ENDRECORD
;RECORD3
;JAY P. MORGAN:606248924
;SECTION 1
"file.m"1@"file.1"3|"file.m"2
"file.m"3|"file.m"4@"file.4"3
;ENDSECTION
;ENDRECORD
ENDBOOK
PRINTRUN R
BOOK A
ENDPRINTRUN
```

In the foregoing example, "file.m" is a file name identifying the master page file **122** and "file.1" and "file.4" are file names identifying the variable page files **137** and **138**, respectively. The number following each file name designates a particular page of the file identified by the file name. Thus, for example, "file.m" 1 designates the first page of the master file "file.m" and "file.1"2 designates the second page of the variable page file "file.1." The @ sign means to associate the pages of the files linked by such sign and the

vertical line in the commands indicates that the page(s) on the left side of the vertical line are to be printed on the front side of a piece of paper whereas the page(s) on the right side of the vertical line are to be printed on the reverse side of the piece of paper. In an example of simplex printing, no file name would appear to the right of the vertical line in each command.

FIGS. 11a–11c illustrate an exemplary imposition system which may be used to impose pages for printing. The imposition system of FIGS. 11a–11c is invoked to create a new press command file which prints at least one, and likely two or more pages on one or both sides of a form. The programming begins at blocks 340 and 342 which open the press command file and select a first record therein. A block 344 then reads such record and a block 346 determines the number of master pages that are in the press command file record read by the block 344. In the example shown in FIGS. 6a and 6b, and as defined in the press command file example set forth above, each book includes four master pages. The block 346 determines the number of master pages in the record to determine page assignments to the various forms. As noted above, “form” designates a single sheet of paper as printed by the press. Each form has two sides, each of which is referred to as a “flat.” Each flat includes a number of pages thereon, wherein the number is hereinafter referred to as the “PPF” number (for “pages-per-flat” number).

A block 348 determines the book or the book version to be produced during the print job having the greatest number of book pages. This book or book version is hereinafter referred to as the “largest book”. A block 350 then prompts a user to enter various imposition parameters including shingling and bottling amounts, placement and appearance of press marks, head direction of each page (when not all pages have the same head direction, for example, as seen in FIGS. 8a and 8b) page position(s) on each flat and any other required imposition parameters. In addition, the user is prompted to enter the PPF number for each flat type to be produced. For example, the user may be prompted to enter a PPF number of two for the examples of FIGS. 6a, 6b and 7a, 7b and a PPF number of four for the example of FIGS. 8a and 8b. The parameters may be specified by a user using any commercially available and suitable imposition system such as Preps®, by ScenicSoft, Inc. of Everett, Wash. Imposstrip®, by Ultimate Technographics of Montreal, Quebec, Canada, Quark Inposition® by Quark, Inc. of Denver, Colo., or any other system. Alternatively, the imposition system disclosed in Sands et al. U.S. patent Ser. No. 738,217, filed Jul. 30, 1991, and entitled “Digital Page Imaging System” can be used.

Following the block 350 a block 352 develops an imposition pattern allowing a block 354 to derive the specified imposition patterns. This step effected by the block 352 is necessary inasmuch as the specified imposition parameters are not directly available to such programming, and hence the parameters must be obtained by selecting the largest book or book version to be produced and imposing same so that the imposition parameters can be deduced therefrom. If the imposition parameters can be provided to the programming of FIGS. 11b and 11c directly, then the blocks 352 and 354 would be unnecessary and may be omitted.

Following the block 354, a block 356, FIG. 11b, associates master and variable pages to appear on the same flat with each other according to the PPF number for such flat to obtain a master/variable page group for each flat. In the example of FIG. 6a, the master and variable files for the pages P1 and P4 would be associated together. In the example of FIG. 8a, the master and variable files for the pages P9, P12, P13 and P16 would be associated by the block 356.

A block 358 then selects a first master/variable page group and a block 360 determines the form depth of the master/

variable page group. The “form depth” is the position of a printed flat in a stack of forms which are stitched together to produce a book.

Following the block 360, a block 362 checks to determine whether the form depth and the identity of the master/variable page group are a unique combination. If so, a block 364 creates a list in the memory 53 of group/depth combination (if such list has not already been created) and adds the current group and form depth combination to such list.

Following the block 364, a block 366 develops and saves a flat pattern defining a template for the master/variable page group, taking into account the form depth of such group. The flat pattern is a file defining the positions of the pages associated as a group by the block 356. A block 368 then creates placeholders for the master data of the master/variable page group in the flat pattern so that a new flat file pattern is obtained. The new flat file pattern is stored in the memory 53 and control passes to a block 370, FIG. 11b. Control also passes directly to the block 370 from the block 362, bypassing the blocks 364–368, if the page group identity and form depth combination is not unique.

The block 370 identifies and selects the flat pattern from the imposed PDL file pattern developed by the block 352 at the form depth of the selected master/variable page group. A block 372, FIG. 11c, then creates place holders for variable data of the master/variable page group in the flat patterns selected by the block 370 to obtain a new flat pattern which is then stored in the memory 53. A block 374 thereafter develops a new press command file entry to reflect the imposed master/variable page group.

Following the block 374, a block 376 checks to determine whether all master/variable groups for the record of the press command file currently under consideration have been processed. If not, a block 378 selects the next master/variable page group and control returns to the block 360 of FIG. 11b. Otherwise, a block 380 checks to determine whether all records in the press command file have been processed. If not, a block 382 selects the next record and control returns to the block 344 of FIG. 11a. If all records have been processed, a block 384 inserts the file data for the master/variable files into the placeholders in the respective flat patterns to develop the imposed master and variable page files 124 and 139 of FIG. 5. A suitable INI file is also created to reflect the new flat geometry.

FIG. 12 illustrates programming which may be executed by the control unit 52 of FIG. 3 to facilitate conversion of the imposed page files 124 and 139 into bitmap format using the RIP 82 of FIG. 4. The programming begins at a block 400 which opens the press command file stored in the memory 53. A block 402 then prompts a user to specify options which are available using the RIP 82. The options include the ability to convert only master page files, only variable page files or both master and variable page files into bitmap format. A block 404 then selects the first line in the press command file having at least one file name therein. Thereafter, a block 406 selects a first file name and a block 408 checks a file list stored in the memory 53 to see if the file name has been previously placed in the list. If this is not the case, then this is the first time the file name has been encountered in the programming of FIG. 12. Thus, a block 410 adds the file name to the file list and a block 412 checks the user-specified options set by the block 402 to determine whether the file should be converted into bitmap format. If so, a RIP list stored in the memory 53 is updated by adding the file name thereto and control passes to a block 416. Control also passes to the block 416 from the block 412 bypassing the block 414 if the file is not to be converted into bitmap format, and from the block 408 if the file name currently under consideration is already in the file list.

The block 416 checks to determine whether the end of the current line in the press command file has been reached. If

not, a block 418 selects the next file name in the line and control returns to the block 408.

If the block 416 determines that the end of the current line in the press command file has been reached, a block 420 checks to determine whether the end of the press command file has been reached. If not, a block 422 selects the next line in the press command file having at least one file name and control returns to the block 406. On the other hand, if the end of the file has been reached, a block 424 causes the RIP 82 to convert the files identified in the RIP list into bitmap format by issuing commands and files as appropriate to the RIP 82.

The programming of FIG. 12 facilitates conversion of files to bitmap format as required by the print system 79.

Numerous modifications and alternative embodiments of the invention will be apparent to those skilled in the art in view of the foregoing description. Accordingly, this description is to be construed as illustrative only and is for the purpose of teaching those skilled in the art the best mode of carrying out the invention. The details of the structure may be varied substantially without departing from the spirit of the invention, and the exclusive use of all modifications which come within the scope of the appended claims is reserved.

We claim:

1. An apparatus for controlling an electronic press wherein the press includes a controller responsive to press commands, comprising:

first means for developing a template file defining pages to be printed with fixed information common to all of the pages and variable information unique to each page; a database having entries therein each representing variable information to be printed;

second means responsive to the first developing means for developing a master page file from the template file wherein the master page file defines the fixed information; and

means responsive to the database and the first and second developing means for converting the template file and the database into press commands specifying sequence and content of page production by the press.

2. The apparatus of claim 1, wherein the converting means includes means for copying the template file to create a copy file and means for stripping data representing the fixed information from the copy file to obtain an intermediate variable page file.

3. The apparatus of claim 2, wherein the intermediate variable page file includes variable area data representing an area of each page to be printed with variable information and wherein the converting means further includes means responsive to the variable area data for inserting entries from the database into the intermediate variable page file to obtain a final variable page file.

4. The apparatus of claim 3, wherein the converting means further includes means for creating the press commands from the final variable page file and the master page file.

5. The apparatus of claim 3, wherein the final variable page file includes text data representing text to be printed on a page and wherein the inserting means includes means for composing the text data.

6. An apparatus for controlling an electronic press wherein the press includes a controller responsive to press commands, comprising:

a database having entries therein each representing variable information to be printed;

first means for developing a plurality of template files each defining associated pages to be printed with and having first data defining fixed information common to all of the associated pages wherein at least one of the

template files further includes second data defining a particular area in each associated page for the printing of variable information therein unique to such page and third data identifying at least one of the database entries;

second means responsive to the first developing means for developing a master page file from the template file wherein the master page file includes data defining the fixed information only; and

means responsive to the database and the first and second developing means for deriving press commands specifying sequence and content of page production by the press from the template files and the database.

7. The apparatus of claim 6, wherein the deriving means includes means for copying each template file to create a copy file and means for stripping data representing the fixed information from each copy file to obtain an intermediate variable page file.

8. The apparatus of claim 7, wherein each intermediate variable page file includes variable area data representing an area of a page to be printed with variable information and wherein the deriving means further includes means responsive to the variable area data for inserting entries from the database into each intermediate variable page file to obtain final variable page files defining content and position of variable information to be printed on associated pages.

9. The apparatus of claim 8, wherein the deriving means further includes means for creating the press commands from the final variable page files and the master page file.

10. The apparatus of claim 8, wherein at least one of the final variable page files includes text data representing text to be printed on a page and wherein the inserting means includes means for composing the text data.

11. A method of controlling an electronic press wherein the press includes a controller responsive to press commands, comprising:

developing a template file defining pages to be printed with fixed information common to all of the pages and variable information unique to each page;

assembling a database having entries therein each representing variable information to be printed;

developing a master page file from the template file wherein the master page file defines the fixed information; and

converting the template files the database and the master page file into press commands specifying sequence and content of page production by the press.

12. The method of claim 11, wherein the step of converting includes the steps of copying the template file to create a copy file and stripping data representing the fixed information from the copy file to obtain an intermediate variable page file.

13. The method of claim 12, wherein the intermediate variable page file includes variable area data representing an area of each page to be printed with variable information and wherein the step of converting further includes the step of inserting entries from the database into the intermediate variable page file responsive to the variable area data to obtain a final variable page file.

14. The method of claim 13, wherein the step of converting further includes the step of creating the press commands from the final variable page file and the master page file.

15. The method of claim 13, wherein the final variable page file includes text data representing text to be printed on a page and wherein the step of inserting includes the step of composing the text data.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 6,327,599 B1
DATED : December 4, 2001
INVENTOR(S) : Warmus et al.

Page 1 of 1
