### Abstract

**Background:** Anemia is a common complication in patients with cancer and other chronic disorders resulting from tumor resection with surgery. The development of an agent that stimulates bone marrow production with sustained erythropoiesis is a major therapeutic goal. Recent reports with the continuous erythropoiesis receptor activator (CERA) (Continuous Erythropoiesis Receptor Activator) are an innovative agent for the treatment of anemia currently in clinical development.

**Purpose and Methods:** The pharmacokinetic and pharmacodynamic properties of CERA were evaluated in rodent and non-human primate models. The pharmacokinetic properties of CERA and specificity were compared in the rat, mouse, monkey, and dog following injection of single doses. The pharmacodynamic properties of CERA and specificity were compared in the rat, mouse, monkey, and dog following injection of single doses. The pharmacodynamic properties of CERA and specificity were compared in the rat, mouse, monkey, and dog following injection of single doses as well as repeated administration over several weeks. In addition, the erythropoietic activity of CERA was tested in non-human primates and monkeys weekly over a period of 6 weeks.

**Results:** In pre-clinical studies, the pharmacokinetic half-life of CERA was much longer than that of epoetin beta. In dogs that received a single injection at a median oral bioavailability (F) of 0.76, the mean AUC<sub>0-t</sub> was 4.3 x 5.24 mg·h/ml and the mean AUC<sub>0-∞</sub> was 4.3 x 5.60 mg·h/ml. The mean AUC<sub>0-t</sub> was 1.2 x 10<sup>-3</sup> mg·h/ml and the mean AUC<sub>0-∞</sub> was 1.2 x 10<sup>-3</sup> mg·h/ml for CERA. A single injection of 20 µg/kg of CERA in mice resulted in an increase in mean reticulocyte counts of 10% (n=12). Administration of 20 µg/kg of CERA in mice resulted in an increase in mean reticulocyte counts of 17.8% (n=12). In rats, a single injection of 20 µg/kg of CERA resulted in an increase in mean reticulocyte counts of 17.7% (n=12). The erythropoietic effect of CERA was initially observed in white tail deer antelope. Subsequent evaluations in rhesus monkeys and dogs showed similar results. In rhesus monkeys, a single dose of CERA (20 µg/kg) resulted in an increase in mean reticulocyte counts of 17.7% (n=12) and a single dose of CERA (20 µg/kg) resulted in an increase in mean reticulocyte counts of 17.8% (n=12). The erythropoietic effect of CERA was initially observed in white tail deer antelope. Subsequent evaluations in rhesus monkeys and dogs showed similar results. In rhesus monkeys, a single dose of CERA (20 µg/kg) resulted in an increase in mean reticulocyte counts of 17.7% (n=12) and a single dose of CERA (20 µg/kg) resulted in an increase in mean reticulocyte counts of 17.8% (n=12).

**Conclusion:** CERA has been shown to stimulate erythropoiesis in rhesus monkeys and dogs following injection of single doses as well as repeated administration over several weeks. In addition, the erythropoietic activity of CERA was tested in non-human primates and monkeys weekly over a period of 6 weeks.

### Background

- Anemia is a very common complication in patients with chronic disorders, with an overall mass of over 50%.
- Low hemoglobin (Hb) levels may be associated with fatigue and other symptoms, resulting in an impaired quality of life.
- There is a considerable anemia rate among women during pregnancy.
- As such, the treatment of anemia is an integral part of cancer management.
- Treatment with recombinant human erythropoietin (rhEPO) has been shown to increase Hb levels, reduce the need for transfusions, and improve quality of life in patients with chronic myelogenous leukemia (CML), a relatively common cancer associated with anemia due to relative aplastic therapy.<sup>1,2</sup>
- An important advance in the management of anemia would be the development of a novel erythropoietic agent that allows for the administration of lower doses of rhEPO.
- The administration of rhEPO to patients with anemia can cause thrombotic events.<sup>3</sup> Despite this, a considerable number of cancer patients with anemia do not tolerate rhEPO therapy.<sup>4</sup>
- An important advance in the management of anemia would be the development of a novel erythropoietic agent that allows for the administration of lower doses of rhEPO.
- CERA is a novel erythropoietic agent.

### Purpose and Methods

- The properties of CERA (Continuous Erythropoiesis Receptor Activator) were assessed in several studies in rodent and dog models. These included pharmacokinetic properties and pharmacodynamic properties. The pharmacokinetic properties were evaluated in 20 studies, 15 studies in ferret non-human primates, and 5 studies in rhesus monkeys.
- The pharmacodynamic properties were evaluated in 12 additional studies. In the dog, in each of these studies, properties of CERA were compared with epoetin beta (EPO).
- CERA has been shown to stimulate erythropoiesis in rhesus monkeys and dogs following injection of single doses as well as repeated administration over several weeks.

- In animal models, the pharmacokinetic properties of CERA are much longer than that of epoetin beta. In dogs that received a single injection at a median oral bioavailability (F) of 0.76, the mean AUC<sub>0-t</sub> was 4.3 x 5.24 mg·h/ml and the mean AUC<sub>0-∞</sub> was 4.3 x 5.60 mg·h/ml. The mean AUC<sub>0-t</sub> was 1.2 x 10<sup>-3</sup> mg·h/ml and the mean AUC<sub>0-∞</sub> was 1.2 x 10<sup>-3</sup> mg·h/ml for CERA. A single injection of 20 µg/kg of CERA in mice resulted in an increase in mean reticulocyte counts of 10% (n=12). Administration of 20 µg/kg of CERA in mice resulted in an increase in mean reticulocyte counts of 17.8% (n=12). In rats, a single injection of 20 µg/kg of CERA resulted in an increase in mean reticulocyte counts of 17.7% (n=12). The erythropoietic effect of CERA was initially observed in white tail deer antelope. Subsequent evaluations in rhesus monkeys and dogs showed similar results. In rhesus monkeys, a single dose of CERA (20 µg/kg) resulted in an increase in mean reticulocyte counts of 17.7% (n=12) and a single dose of CERA (20 µg/kg) resulted in an increase in mean reticulocyte counts of 17.8% (n=12).
- Administration of CERA resulted in a dose-dependent and specific erythropoietic response. A single subcutaneous (SC) injection of CERA 20 µg/kg in mice (body weight) resulted in an increase in mean reticulocyte counts of 10%. Administration of a single SC injection of CERA that was compared with the same dose of epoetin (CERA 20 µg/kg), indicating the higher erythropoietic potency of CERA. In addition, the median duration of response of CERA was noted as CERA was 3 days longer than that of epoetin with epoetin.
- Mean erythrocyte counts were also increased in response to CERA compared with epoetin (Figure 1). No significant changes were observed in white tail deer antelope and monkeys, suggesting safety of CERA because no toxicity or adverse effects were observed in CERA treated animals.

Table 1. Average pharmacokinetic parameters of CERA compared with epoetin following SC and IV administration

IV administration in days CERA 20 µg/kg (n=4) Epoetin 20 µg/kg (n=3)

Gavage 0.3 (0.2-0.4) 0.2 (0.1-0.3)

IV (single) 50 (42-64) 78 (65-85)

IV (2x) 49 (29-65) 61 (58-68)

AUC<sub>0-t</sub> (µg·h/ml) 328 (218-401) 320 (201-301)

IV administration in days CERA 2.5 µg/kg (n=3) Epoetin 2.5 µg/kg (n=3)

Gavage 0.1 (0.05-0.16) 0.1 (0.05-0.16)

IV (single) 50 (25-60) 50 (35-60)

IV (2x) 50 (25-50) 50 (35-50)

AUC<sub>0-t</sub> (µg·h/ml) 320 (225-320) 364 (272-314)\*\*Significant difference between CERA and epoetin in terms of AUC<sub>0-t</sub> (p<0.05) by unpaired t-test.

†p < 0.05 vs epoetin and 13.7 x 10<sup>12</sup> RBCs/dl of blood at 5.0 g/dL Hb‡Administration of CERA 20 µg/kg increased reticulocytes count in 12.8 x 10<sup>12</sup> RBCs/dl of blood at 5.0 g/dL Hb.§Administration of CERA 20 µg/kg increased erythrocytes count is 12.8 x 10<sup>12</sup> RBCs/dl.

¶The erythropoietic effects of CERA were similar to epoetin following SC and IV administration of a single 2.5 µg/kg dose to mice (n=3). Both in terms of the magnitude and duration of response (Figure 2).

\*\*The erythropoietic effects of CERA were similar to epoetin following SC and IV administration of a single 20 µg/kg dose to rhesus monkeys (n=3) both in terms of the magnitude and duration of response (Figure 3).

\*\*\*The erythropoietic effects of CERA were similar to epoetin following SC and IV administration of a single 20 µg/kg dose to dogs (n=3) both in terms of the magnitude and duration of response (Figure 4).

\*\*\*\*The erythropoietic effects of CERA were similar to epoetin following SC and IV administration of a single 20 µg/kg dose to white tail deer antelope (n=3) both in terms of the magnitude and duration of response (Figure 5).

- CERA may also known to be a more potent stimulator of erythropoiesis than epoetin in humans as well as in animals. The duration of erythropoietic response was increased with CERA compared with epoetin following both SC and IV administration.
- Administration of CERA to non-human primates (n=3-12), a higher number of chronic renal failure and erythropoietic agents were used in comparison to epoetin. No such increase was observed in animals treated with CERA. Once- and twice-dosander therapy was used in all animals. The duration of response was also observed following treatment with CERA. These findings were consistent with those seen in studies of normal animals.

### Conclusions

- CERA is an innovative new erythropoietic agent with a lower systemic clearance and an increased serum half-life compared with epoetin.
- In animal studies, CERA appears to be a more potent stimulator of erythropoiesis than epoetin, both with regard to magnitude and duration of response.
- The observed erythropoietic effect of CERA is dose-dependent and specific.
- Erythropoietic response is comparable after both SC and IV administration of CERA.
- The unique pharmacodynamic and pharmacokinetic properties of CERA suggest that it may represent a significant development in the treatment of anemia, offering enhanced erythropoietic activity and the opportunity of increased dosing intervals for greater flexibility and convenience.

Abstract: CERA is a novel erythropoietic agent for the treatment of anemia. Pharmacokinetic properties of CERA were investigated in animal models and in 2 placebo-controlled studies of healthy male volunteers randomized to receive single doses of CERA 0.4-3.2 µg/kg by intravenous (IV) injection or CERA 0.1-3.2 µg/kg by subcutaneous (SC) injection. In addition, the erythropoietic activity of CERA was compared with that of epoetin using a normocytic mouse model and *in vitro* using a UT-7 (human myeloid leukemia cell line) proliferation assay. Binding to the erythropoietin (EPO) receptor was compared *in vitro* using a soluble EPO receptor-binding assay. Median serum half-life of CERA was 7-fold greater than that of epoetin following IV injection in dogs (49.0 vs 6.4 h). In healthy volunteers, mean serum half-life for CERA ranged between 70-122 h after IV and 102-146 h after SC administration depending on dose. AUC and Cmax increased more than proportionally with dose. In the receptor-binding assay, association rates of CERA and epoetin with soluble EPO receptor were similar whereas the dissociation rate of CERA was higher than that of epoetin. CERA had greater erythropoietic activity than epoetin in the normocytic mouse but not *in vitro* (dose range 0.003-3 U/ml). Taken together, these data suggest that CERA binds less tightly to the EPO receptor and dissociates more quickly compared with epoetin. A novel mode of action is proposed by which rapid dissociation from the erythropoietin receptor together with an extended serum half-life result in an enhanced and sustained erythropoietic effect through continuous modulated stimulation of erythropoiesis. These pharmacokinetics may lead to enhanced erythropoietic activity, less frequent dosing and optimal patient outcomes.
