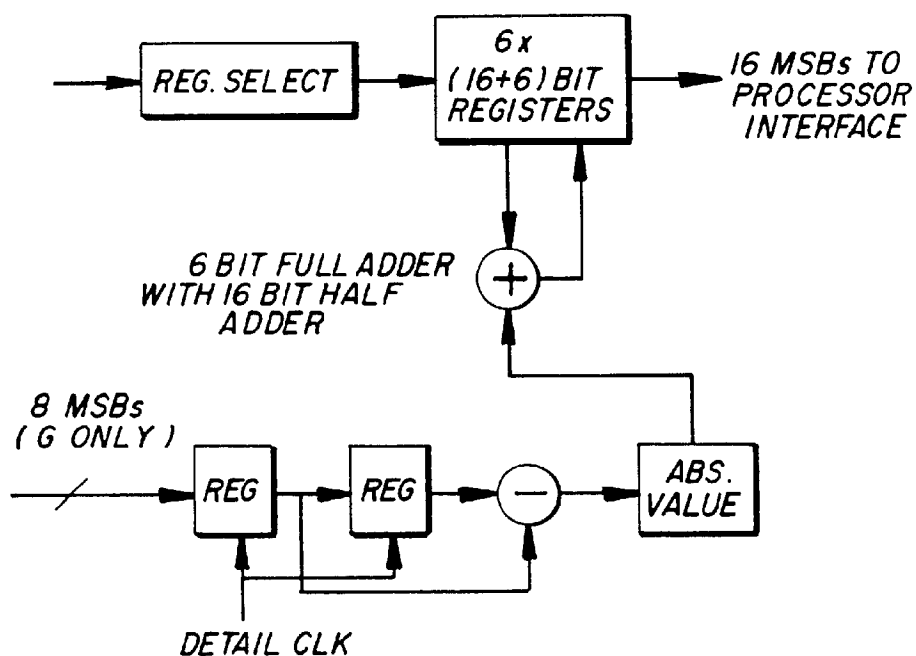

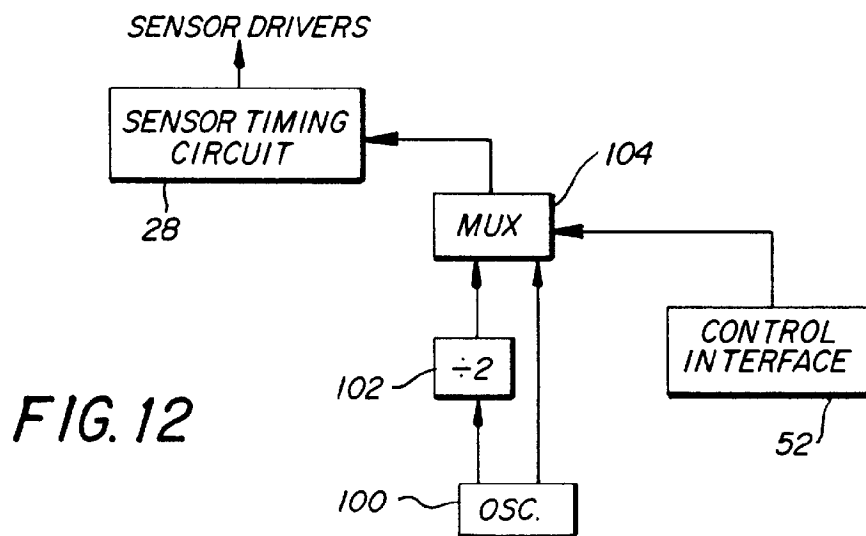

FIG. 9B

ELECTRONIC CAMERA FOR INITIATING CAPTURE OF STILL IMAGES WHILE PREVIEWING MOTION IMAGES

This application is a division of 08/367,399 filed Dec. 30, 1994.

FIELD OF THE INVENTION

The invention pertains to an electronic still camera for composing and capturing still images, and, more particularly, to an electronic camera having a "motion" mode for previewing a scene and a "still" mode for capturing a particular image in the scene.

BACKGROUND OF THE INVENTION

Consumer camcorders which include the capability of recording analog motion and/or still images on 8mm or VHS videotape have been developed by a number of companies. Motion images are recorded in the same manner as in any standard camcorder. These cameras include a single chip charge coupled device (CCD) sensor having a color filter array that provides a spatially color-sampled image. To record still images, the user pushes a "still capture" button at the desired instant. The image obtained from the CCD sensor is temporarily stored in a digital memory. The image is then read from the memory and recorded onto the videotape. Some camcorders include color liquid crystal displays (LCD), which are also spatially color-sampled devices. Some are relatively large, for example, ranging from approximately 2.5" to 4" in diagonal. Such a display is used, instead of a normal eyepiece viewfinder, to allow the user to properly frame the subject and view the images as they are being recorded. It is also used to view the recorded images as the videotape is played back.

FIG. 1A shows a typical color LCD display, in which the liquid crystal material is trapped between an upper glass plate 1 and a lower glass plate 2. The upper plate 1 has a common transparent electrode 3 and an array 4 of color filters surrounded by a black mask 5. The lower plate 2 includes an array 6 of transparent pixel electrodes juxtaposed underneath the array 4 of color filters. Individual pixel electrodes are activated via thin film transistors (TFT) 7 that are controlled from a video signal on the source lines 8 and a scanning signal on the gate line 9. The LCD display includes the usual polarizer layers (not shown) on the glass plates 1 and 2, such that activation of selected transparent pixel electrodes allows light to pass through the corresponding color filters and reflect to the viewer, thereby creating a color image. A typical LCD display such as the Epson LB 2F-BC00, manufactured by Seiko-Epson Company, Japan, has about 240 lines of pixels and about 300 pixels per line, with an image aspect ratio of 4:3. Such an aspect ratio allows the entire area of the image obtained from the 4:3 aspect ratio NTSC format CCD sensor to be displayed on the LCD screen, so that the LCD screen composition will be the same as the image that is recorded by the camcorder NTSC format recorder, for later display on an NTSC format television display. Note that because the LCD has only 240 lines of pixels, the interlaced NTSC signal is displayed using a "repeat field" technique, where both the odd and even fields from the NTSC format sensor are displayed using the same lines of pixels on the LCD. This LCD, like most commercially available LCDS, has "rectangular" pixels, rather than square pixels, where the distance between pixels in the horizontal direction is for example $\frac{2}{3}$ the distance in the vertical direction. The LCD pixels are overlaid with a diagonal RGB stripe pattern as shown in FIG. 1B.

In camcorders, the processing for both the still images and the motion images is identical. Such processing is normally implemented by hardwired analog integrated circuits, although camcorders which use digital image processing integrated circuits have been produced. Such camcorders convert the signal from the CCD sensor into an NTSC composite or component format signal, which is provided to a video recording subsystem or a video output jack. The color LCD display includes circuitry to decode the NTSC composite or component signal back into spatially subsampled RGB signals to drive the individual RGB pixels on the LCD sensor.

In a system oriented toward still photography, and in particular a digital still system, it would be desirable to avoid the necessity of generating an NTSC format signal in order to reduce the complexity of the required circuitry. In a totally digital system, that is, both the recording and display channels are digital, it is further desirable to minimize incompatibility between the channels. The problem is to achieve these objective in an architecture that minimizes cost and complexity and maximizes user handling.

SUMMARY OF THE INVENTION

This problem is solved according to the invention by a number of features. In one aspect, the electronic camera is operable in a still image mode according to a relatively more complex digital image processing technique to produce high quality still images, and in a motion preview mode according to a relatively more simple digital image processing technique to produce a preview image of acceptable quality prior to initiation of the still image mode. Such an architecture is particularly adapted to mapping an array of color image pixels from a sensor into an array of color display pixels on an LCD display comprising discrete LCD display pixels fewer in number than image sensor pixels. In that case, a relatively simple digital processing technique combines samecolored image pixel signals into a fewer number of intermediate pixels that correspond to the arrangement of the color display pixels.

The advantage of the invention is that the two modes can be tailored for a relatively low quality "motion" mode and a much higher quality "still" mode. The motion mode images from the CCD sensor are processed by a hardwired digital signal processing circuit that generates low resolution, spatially subsampled digital image data which can directly drive the relatively low resolution LCD display. This reduces the complexity and clock frequency of the required circuitry, compared to generating an NTSC format signal, as is normally done in the prior art. The still mode image from the CCD sensor is processed by a general purpose processor (CPU) which executes an image processing software program in order to produce a high quality digital still image.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be described in relation to the drawings, whereon

FIGS. 1A and 1B show the structure and color filter pattern of a known color liquid crystal display (LCD);

FIG. 2 is a block diagram of an electronic camera incorporating dual modes for composing and capturing a still image according to the invention;

FIGS. 3A and 3B are diagrams of progressive scan image sensors useful with the camera of FIG. 2;

FIG. 4 is a diagram of the Bayer color filter geometry for the sensor used with the camera of FIG. 1;

FIG. 5 shows the line timing for the still mode of operation;

FIGS. 6A and 6B show the line timing for the preview mode of operation;

FIG. 7 shows the special line skipping pattern used in the preview mode;

FIG. 8 shows further detail of the preview mode processing circuit shown in FIG. 2;

FIGS. 9A and 9B show further detail of the image statistics processor shown in FIG. 2;

FIG. 10 shows one example of still mode image processing;

FIG. 11 shows the effect of pixel mapping from a sensor to an LCD display, each having different aspect ratios; and

FIG. 12 shows an enhancement to the block diagram of FIG. 2 in which a different sensor clock frequency is used in each of the dual modes.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

A block diagram of a camera incorporating dual modes of processing according to the invention is shown in FIG. 2. The camera includes an electronic color display, for example, a color liquid crystal (LCD) display 10 of the type shown in FIG. 1A, and a user control section 12 having a number of user control buttons, including zoom buttons 14, a preview button 15 and a capture button 16. To take a still picture, the user turns on the camera (using a power switch (not shown), which may be automatically enabled when the user depresses the zoom buttons 14 or the preview button 15, or partially depresses the capture button 16). The user composes the picture by depressing the "zoom in" or "zoom out" buttons 14, and by adjusting the position of the camera, while observing the display image. When the user is satisfied with the composition on the color LCD display 10, the user depresses the capture button 16. The camera then captures a single still image, firing a flash 18 if necessary when the ambient illumination level is low. The still image is focused upon an image sensor 20 by a motor driven zoom lens 22. The intensity of the image light upon the sensor 20 is regulated by a motor-driven, variable, mechanical aperture 24, while exposure time is regulated electronically by appropriate clocking of the sensor 20. The still image from the image sensor 20 is processed and digitally stored on a removable memory card 26.

Control of the sensor is provided by a timing and control section 27, which is an application specific integrated circuit (ASIC) with processing and timing functions, for both capture and preview operating modes. For instance, the timing and control section 27 includes a sensor timing circuit 28 for controlling the image sensor functions. The sensor timing circuit 28 provides the signals to enable sensor drivers 30, which provide horizontal clocks (H1, H2), vertical clocks (V1, V2), as well as a signal FDG for activating a drain structure on the sensor 20. The output of the image sensor 20 is amplified and processed in an analog gain and sampling (correlated double sampling (CDS)) circuit 32, and converted to digital form in A/D converter stage 34. The A/D output signal is provided to a processor section 35, which includes a digital processor 36 for temporarily storing the still images in a DRAM memory 38. The digital processor 36 then performs image processing on the still images, and finally stores the processed images on the removable memory card 26 via a memory card interface circuit 40, which may use the PCMCIA 2.0 standard interface. An

EPROM memory 42 is used to store the firmware which operates the processor 36. The components of the processor 35 are interconnected through a data bus 43, which also connects to the timing and control section 27 and to the card interface 40.

The motor-driven zoom lens 22 includes a zoom motor 44, a focus motor 46, and an aperture motor 48 (all controlled by lens motor drivers 50). The timing and control section 27 further includes a control interface 52 connected to the lens motor drivers 50 and to a flash control circuit 53 via a photosystem interface block 54, which controls the operation of the zoom lens 22 and the flash 18. The lens zoom position is controlled by the photosystem interface block 54 based on position input from the zoom control buttons 14 through a user status and control section 55. The focusing, exposure control, and white balance is done automatically, as is typically the case in consumer camcorders. This is done by computing "image statistics" in an image statistics processor 60 in the real-time ASIC (timing and control section 27) as preview images are continuously read out of the image sensor 20. The computed values are then used by a program implemented in the digital processor 36, which decides how to adjust the focus motor, aperture, analog gain control, and analog white balance controls via the control interface 52 and the photosystems interface 54 on the ASIC timing and control section 27. Although the digital processor 36 and the control interface 52 are shown as being within two separate sections, in some implementations the same component could be used to perform both of these functions (as well as other of the recited functions). Sensor image data is passed to the processor section 35 through a high speed interface 56 in the timing and control section 27. The sensor image data is also directed to the color LCD display 10 through a preview mode processing circuit 58.

The timing and control section (ASIC) 27 is operable in two modes, a relatively low quality "motion" mode and a much higher quality "still" mode. In the motion mode, images from the sensor 20 are processed by the preview mode processing circuit 58; in the still mode, images from the sensor 20 are processed in the processor 35. The processor 35 is a software driven digital processing system that is slower than the ASIC 27. The preview mode processing circuit 58 is a hardwired digital signal processing circuit (part of the ASIC 27) that generates low resolution, spatially subsampled digital image data which can directly drive the relatively low resolution color LCD display 10. This reduces the complexity and clock frequency of the required circuitry, compared to generating an NTSC format signal, as is normally done in the prior art. The preview mode processing circuit includes a pixel remapper 62 for mapping the greater number of image pixels from the sensor 20 into the lesser number of display pixels (i.e., corresponding to the array 6 of transparent pixel electrodes in FIG. 1) in the color LCD display 10. The color saturation of the remapped pixels is then adjusted in a color adjustment circuit 63 and its output is applied to a multiplexer 64. The multiplexer 64 selects image data either from the preview mode processing circuit 58, producing a preview image, or from the high speed interface 56, which allows for suitably preprocessed viewing of stored images.

In this camera, the image processing used to create the preview mode is done in the timing and control ASIC 27, since the processing must be done rapidly. About 60 images per second are processed in preview mode. However, since the image quality of the displayed image is limited by the resolution and color gamut of the LCD screen of the LCD color display 10, there is no need for elaborate image

processing. Therefore, simple "preview mode" image processing is performed in a fixed digital circuit embedded in the preview mode processing circuit 58 (which is part of the ASIC). The quality requirements for the still mode are much greater, since these images will be downloaded to a computer, and may be displayed on a high resolution CRT display, or printed on a high quality thermal printer. Therefore, the digital image processing must be more elaborate. By using the digital processor 36 to implement software procedures stored in the firmware memory 42, complex procedures can be implemented. These procedures can take several seconds to complete, since real-time operation is not required. Use of firmware-stored software allows the still mode image processing to be upgraded without requiring a new ASIC design. In effect, what happens is that a relatively less complex digital image processing technique is used in the motion preview mode, but at a higher data rate, and a relatively more complex digital image processing technique is used in the still mode, but at a slower data rate.

Since the update rate, that is, the number of images that need to be supplied per unit time, is different for the still mode than for the motion mode, it is beneficial to use different clock frequencies for the different modes of operation. For example, as shown in FIG. 12, a system oscillator 100 produces a 12 MHz clock frequency for use in the motion mode to obtain more updates/second (e.g., 60 images per second), while a divider 102 divides by two to provide a 6 MHz clock frequency for the still mode. The lower frequency allows more time to accurately position the clamp and sample pulses so as to avoid CCD output signal transitions. This increases noise immunity in the still mode. A multiplexer 104 is enabled by the control interface 52 to determine which clock frequency is applied to the sensor timing circuit 28. Though not specifically shown, the changed timing is also communicated to the A/D stage 34 and other timing and control circuits.

The sensor 20 is a progressive scan interline image sensor having a noninterlaced architecture, as shown in more detail in FIG. 3A. The sensor comprises a two-dimensional array of photosites 66, e.g. photodiodes, arranged in rows and columns of image pixels, a plurality of vertical registers 68 adjacent photosite columns for transferring rows of image pixel charge from the photosites 66 to a horizontal register 70 for readout responsive to clock signals from the sensor drivers 30, and a charge drain (specifically, a fast dump structure 72) interposed between the output of the vertical registers 68 and the horizontal register 70 for eliminating complete rows of image pixels at a time from the image sensor 20. A preferred image sensor is the Kodak model CCD KAI-0400CM image sensor, which has approximately 512 active lines with approximately 768 active pixels per line and an image aspect ratio of 3:2. This sensor is described in a Performance Specification document available from Eastman Kodak Company, Rochester, N.Y. Each pixel is 9 microns "square", since both the vertical and horizontal distances between the centers of adjacent pixels are 9 microns. The 3:2 image aspect ratio of the CCD sensor, although wider than the 4:3 aspect ratio of the display, is considered to be a preferred aspect ratio for still photography, in that the standard 35 mm film format, and standard 4R (4"x6") prints also have a 3:2 image aspect ratio. The sensor uses a color filter array pattern known as the "Bayer checkerboard" pattern, described in U.S. Pat. No. 3,971,065, which is shown in FIG. 4. Such a color filter array is characterized by a mosaic pattern in which the filter colors alternate in both line and column directions. In the normal operating mode, all of the image pixels on the sensor are

transferred as color image pixels to the horizontal register 70, which delivers a stream of color pixel signals to the analog gain and CDS circuit 32 (see FIG. 2). The color pixel signals are subsequently converted to digital pixel signals in the A/D converter 34.

The sensor 20 uses a progressive scan readout method, which allows the entire image to be read out in a single scan. The accumulated or integrated charge for the photodiodes comprising the pixels 66 is transported from the photosites to light protected vertical (parallel) registers 68 by applying a large positive voltage to the phase-one vertical clock (V1). This reads out every row, or line, into the vertical registers 68. The image pixel charge is then transported from the vertical registers 68 to the horizontal register 70 by two-phase clocking of the vertical clocks (V1, V2). Between the vertical and horizontal registers is the fast dump structure 72, which is further described in the Performance Specification document for the KAI-0400CM sensor. By setting a suitable positive potential on a fast dump gate line FDG, charge from the row of pixel values currently adjacent to the fast dump structure 72 is transferred from the CCD directly into the sensor substrate 74 rather than to the horizontal register 70. This dump, or line clear, is accomplished during the vertical-to-horizontal transfer time. When properly controlled by the sensor timing circuit 28, the fast dump structure 72 allows lines of charge to be eliminated.

The timing and control section 27 operates the electronic camera shown in FIG. 2 in the two aforementioned modes, including a first "still" mode wherein all rows of image pixel charge corresponding to each line are progressively read out through the horizontal register 70 during a single scan, and a second "motion" mode wherein some of the rows of image pixel charge corresponding to some lines are eliminated through the fast dump structure 72 prior to readout. As applied to the embodiment of FIG. 2, the first mode corresponds to a high quality still imaging mode while the second mode corresponds to a special "line skipping" mode for driving the color LCD display 10. In the second mode, the timing and control section 27 controls the fast dump structure 72 to eliminate two or more consecutive lines of image charge from the image sensor 20 for every one or more lines of image charge that are transferred to the horizontal register 70 for readout, thereby generating a pattern of lines (shown in FIG. 7) suitable for driving the LCD display in a "repeat field" mode. An appropriate video signal which displays the entire 3:2 aspect ratio sensor image on the 4:3 aspect ratio LCD, without introducing geometric distortion, is generated by alternately eliminating two or four consecutive lines of image charge for every pair of lines of image charge that are transferred to the horizontal register 70.

The sensor timing circuit 28 is controlled by the control interface 52 to provide the clock signals V1, V2, H1, H2, and the gate signal FDG according to the two modes of operation. The timing signals for the first mode are shown in FIG. 5; those for the second mode are shown in FIGS. 6a and 6b. The two-phase cycling of signals V1 and V2 control the transfer of lines of image pixel charge from the vertical registers 68 to the horizontal register 70. The two-phase cycling of signals H1 and H2 control the transfer of a stream of color pixel signals from the horizontal register 70 to subsequent circuits in the camera. The level of the signal FDG determines whether the image charge is dumped to the substrate 74 or transferred to the horizontal register 70. When the sensor 20 is clocked using the first timing mode shown in FIG. 5 for all lines of the sensor, all lines of the sensor are clocked out, one after the other, through the horizontal register 70, processed in subsequent camera

circuitry, and stored in the removable memory 26. This timing mode provides a high quality progressive scan still image, but may take $\frac{1}{30}$ second or longer to read out the still image. Such timing, however, is acceptable for still mode usage, and, as mentioned before, does not require unusually high speed components and, indeed, may benefit from a lower speed lock.

To provide an image to the color LCD display 10, a lower resolution image is suitable, but the update rate must be sufficient to provide good motion rendition and eliminate display flicker. Moreover, the sensor 20 includes the aforementioned array of color filters arranged in a particular mosaic color pattern (e.g., the checkerboard Bayer pattern of FIG. 3), and the lines of image charge that are transferred to the horizontal register 70 should preserve that particular color pattern in the pattern of lines that are generated for the line-skipping readout. To provide this kind of image, the sensor is read out in the second mode as shown in FIG. 7, using the timing shown in FIGS. 6A and 6B. As shown in FIG. 6A, the first two lines (1 and 2) are read out as in the normal mode. These provide a green-red and a blue-green line. The next two lines (3 and 4) are eliminated by turning on the fast dump structure 72 during the time that these lines are transferred past the fast dump structure 72. Next, as shown in FIG. 6B, lines 5 and 6 are read out normally, and then lines 7, 8, 9, and 10 are eliminated. Next, the FIG. 6A timing is used to read out lines 11 and 12, while eliminating lines 13 and 14, and then the FIG. 6B timing is used to read out lines 15 and 16, while eliminating lines 17-20. This process proceeds for the entire image readout period, during which 102 pairs of lines are read out, and 154 pairs of lines are eliminated.

This special "line skipping" readout mode, as shown in FIG. 7, allows the sensor 3:2 aspect ratio image to be fully displayed on a 4:3 aspect ratio LCD without "geometric distortion", that is, without stretching the image vertically, and without cropping off the horizontal edges of the image from the image sensor. This allows the LCD to properly show the entire 3:2 aspect ratio image captured by the sensor, so that an image can be properly composed.

As the 512 lines of the CCD imager are read out using the special "line skipping" mode, they are displayed using only 204 out of the approximately 240 LCD lines of pixels. The remaining approximately 36 lines can either be masked behind a bezel, so that they are not visible, or preferably may be used to display status information, such as the time-of-day, image number, or a "push-button menu" for the user buttons. FIG. 11 shows a useful application of such conversions. A sensor having a 3:2 aspect ratio is shown mapped into an image area 90 of an LCD display screen 92 having a 4:3 aspect ratio. A proportional remapping leaves a status area 94 available for other purposes, specifically to show text indicating the function of a set of reconfigurable control buttons 96 in the control section 12. The function of the buttons is specified by the user status and control section 55 (FIG. 2). This status information graphics data can be supplied by the digital processor to the LCD 10 via high speed interface 56, when the MUX 64 is controlled so as to use the digital data from interface 56, rather than from circuit 58, for supplying data to the final approximately 32 lines of the display 10.

The "line skipping" readout causes some minor vertical sampling artifacts, but these are not noticeable in the small LCD displays. The pixels output for the sensor 20 in line skipping mode continue to have the Bayer-type color filter repeating pattern, so that they can be processed using processing techniques designed for the Bayer pattern.

The processing complexity of the camera of FIG. 2 is considerably simplified by directly mapping the RGB sensor pixels 66 to the RGB pixels of the display 10. The easiest way to do this for the image sensor 20 (512 lines \times 768 pixels and 3:2 aspect ratio) is to have an LCD display with 512 \times 768 pixels and the same aspect ratio and color filter pattern. However, this would be a custom, costly LCD. Instead, LCDs have fewer display pixels than image pixels on the image sensor, normally have a 4:3 image aspect ratio, and use the diagonally striped RGB pattern shown in FIG. 1B. In this discussion, an LCD pixel array of about 240 lines \times 312 pixels per line is assumed.

Therefore, the sensor pixels are processed in a "pixel mapping circuit", such as the LCD pixel remapper 62. A block diagram of this circuit is shown in FIG. 8. Note that there are $768/2=384$ green or red/blue pixels per line on the sensor (see FIG. 4). There are about $300/3=100$ green, red, or blue pixels per line on the LCD (see FIG. 1B). Thus, there are approximately $\frac{1}{4}$ as many LCD pixels per line (per color) as there are sensor pixels per line. Therefore, the basic plan is to combine same-colored image pixels into a fewer number of intermediate, combination pixel signals that are then mapped into the color display pixels. For instance, a simple "pixel mapping" circuit maps four green sensor pixel signals into one green LCD pixel for one line by summing two green sensor values, spaced apart by 4 CCD pixel positions, in the green pixel summer 76 and dividing by two via bit-shift wiring. The necessary delay is provided by the registers 82 clocked at one fourth the pixel rate, further delayed by one pixel clock. It also maps four red sensor pixels into one LCD pixel in the same manner (using the red/blue summer 78), and also stores this value in a 100 pixel FIFO 80. The FIFO 80 compensates for the fact that the sensor has line sequential red and blue pixels, by supplying blue pixels on the red sensor lines, and red pixels on the blue sensor lines. Four pixel delays are provided by the registers 82' clocked at one fourth pixel rate (CLK/4). The mapping process is basically, therefore, a process which, in its simplest form, involves averaging of signals to produce a smaller number of output color pixels than input color pixels. (The CFA interpolation algorithm discussed in reference to FIG. 10, on the other hand, produces a larger number of "output" color pixels than input color pixels.) Alternate groups of 2 or 4 lines of sensor values are discarded during preview mode by using the fast dump gate shown in FIG. 3A, as described in connection with the "line skipping" mode. This allows the sensor readout time to be decreased by more than $\frac{1}{2}$ during the preview mode.

Another feature of the design is that by removing the NTSC rate driving circuitry from the color LCD display 10, the active matrix LCD can be updated at a slower frequency than is normally used. This reduces the cost and power consumption of the LCD driver circuits (not shown). For example, the LCD can be updated at 30 Hz (provided the LCD active matrix display is designed so as not to exhibit noticeable flicker at this update rate), instead of 60 Hz.

Once the LCD pixel values are calculated, the LCD color adjust circuit 63 increases the color saturation of the image by forming R-G and B-G color difference signals, and adding or subtracting a fraction of these signals in an array 84 of adders and subtractors from the original RGB signals in order to increase the color saturation of the displayed image. This circuit performs a similar function as a 3 \times 3 color matrix, but uses less hardware and provides less color accuracy. The color accuracy is not critical for the LCD display, however, due to the limited color reproduction quality of such displays. The color reproduction of the still

image is much more important, and is done with a more complicated and precise color correction method with the stored firmware in EPROM 42.

FIGS. 9A and 9B show the processing in the image statistics processor 60, which computes real-time values for both still and motion image capture, all during the preview mode. These values include 24 R, G, and B averages used to set white balance and exposure, and 6 average high frequency "detail" values used to set focus. The 24 RGB averages for white balance are calculated for a group of 4x6 rectangular image regions, for each of R, G, and B; a block diagram of the calculation in one color is shown in FIG. 9A. The 6 average "detail" values for focusing are calculated for green pixels only by accumulating the absolute value of the differences between nearby green values; a block diagram of this calculation is shown in FIG. 9B. These values are computed for each preview image and downloaded to the processor 36. The processor 36 implements a firmware stored procedure which determines the optimum exposure parameters (exposure time, f/stop, and analog gain), white balance settings, and lens focus setting. For the still mode, the processor 36 also decides, based on the last preview images, whether to fire the flash, and determines the optimum exposure parameters, white balance settings, and lens focus setting for the still mode.

Once the still image is captured, the digital processor 36 implements the stored firmware procedures to process and store the still image. FIG. 10 shows a diagram of one possible still image processing method. The CFA interpolation diagram may include the green interpolation method described in U.S. patent application Ser. No. 085,520, filed Jun. 30, 1993, in the name of the same assignee as the present application, and the chrominance interpolation method described in U.S. Pat. No. 4,642,678, both of which are incorporated herein by reference. The color matrix, tone correction, and edge enhancement steps may be similar to those described in U.S. Pat. No. 5,189,511, also incorporated herein by reference. The image compression method may be the JPEG standard compression technique.

The foregoing description envisions taking a single still picture following the motion preview mode. The camera can also optionally capture "bursts" of high quality still images into the DRAM memory during the "still" mode, which are then processed as shown in FIG. 10. Owing to the flash recharge time and other limitations of the "burst" mode, the "burst" mode could utilize different exposure parameters (exposure time, aperture, analog gain, flash, and digital processing) than either the motion or the single still mode.

The invention has been described with reference to a preferred embodiment. However, it will be appreciated that variations and modifications can be effected by a person of ordinary skill in the art without departing from the scope of the invention. For instance, FIG. 3B shows a progressive scan sensor with two readout registers 86 and 88 (which corresponds to the Performance Specification document for the Kodak KAI-031CM image sensor; the preferred embodiment of FIG. 3A simply uses but one register). The purpose is to eliminate the FIFO line delay 80 in the LCD pixel remapper 62. The pairs of lines read out by the registers include both a green/red line and a blue/green line. Therefore, by adding an analog multiplexer between the outputs of the two channels and the analog gain and CDS block 32, which is switched at 1/2 the sensor horizontal clock rate, it is possible to obtain a GRBG sequence of sensor data values at the output of the A/D stage 34. The LCD pixel remapper 62 can then be designed to map from the CCD sensor color pixel pattern to the required RGBRGB LCD

pixel pattern, without using a line delay. Since two CCD lines are read out in parallel, for each LCD line, fewer lines are eliminated via the fast dump gate than for the single-register sensor shown in FIG. 3A.

In particular, if the dual register CCD in FIG. 3B had 512x768 square pixels with a 3:2 aspect ratio, and the LCD had approximately 240 display lines and a 4:3 aspect ratio, the CCD readout would involve fast dumping one pair of lines for every four pairs of lines read out from the CCD sensor. The pixel readout procedure for the horizontal registers can then be varied depending on the mode of operation: both registers are used for the motion imaging mode and one register is used for the still imaging mode. Furthermore, although the Bayer pattern was described, other mosaic-type filter patterns could be used to advantage, for example, complementary patterns involving cyan, magenta, yellow and green filters. The processing for the LCD pixel remapper 62 and the LCD color adjust circuit 63 would be accordingly modified to account for the different color arrangement.

PARTS LIST

- 1 upper plate
- 2 lower plate
- 3 common transparent electrode
- 4 array of color filters
- 5 black mask
- 6 array of transparent pixel electrodes
- 7 thin film transistors
- 8 source lines
- 9 gate line
- 10 color LCD display
- 12 control section
- 14 zoom buttons
- 15 preview button
- 16 capture button
- 18 flash
- 20 progressive scan interline
- 22 zoom lens
- 24 mechanical aperture
- 26 memory card
- 27 timing and control section
- 28 sensor timing circuit
- 30 sensor drivers
- 32 analog gain and CDS
- 34 A/D converter
- 36 digital image processor
- 38 DRAM memory
- 40 card interface
- 42 EPROM memory
- 44 zoom motor
- 46 focus motor
- 48 variable aperture
- 50 lens motor drivers
- 52 control interface
- 53 flash control circuit
- 54 photosystems interface
- 55 user status and control section
- 56 high speed interface
- 58 preview mode processing circuit
- 60 image statistics processor
- 62 pixel remapper
- 63 color adjustment circuit
- 64 multiplexer
- 66 pixel
- 68 vertical readout register
- 70 horizontal register

72 fast dump structure
 74 sensor substrate
 76 green pixel summer
 78 red/blue summer
 80 fifo
 82 two pixel delay registers
 84 array
 86 first readout register
 88 second readout register
 90 image area
 92 LCD display screen
 94 status area
 96 reconfigurable buttons
 100 oscillator
 102 divider
 104 multiplexer

What is claimed is:

1. An electronic still camera for initiating capture of a still image while previewing motion images on a display, comprising:

- (a) an image sensor having a two-dimensional array of photosites covered by a mosaic pattern of color filters including at least three different colors for capturing images of a scene, each captured image having a first number of color pixel values provided in a first color pattern;
- (b) motion processing means for generating from the captured images, a second number of color pixel values provided in a second color pattern having at least three different colors and representative of a series of motion images to be previewed, the second number of color pixel values being less than the first number of color pixel values, and the second color pattern being different from the first color pattern;
- (c) a color display for presenting at least some of the motion images of the series of motion images corresponding to the captured images of the scene, the color display having an arrangement of color display pixels including at least three different colors in a pattern different from the first color pattern;
- (d) a capture button for initiating capture of a still image while previewing the motion images presented on the color display;
- (e) still processing means for generating a third number of color pixel values including at least three different colors representative of a processed captured still image; and
- (f) a digital memory for storing the processed captured still image.

2. The electronic still camera of claim 1 further including a multiplexer having first and second inputs and an output, wherein the first input is coupled to the first processing means, the second input is coupled to the second processing means, and the output is coupled to the display so that a captured still image can be viewed on the display.

3. The electronic still camera of claim 1 wherein the first processing means and the second processing means are integrated into a single integrated circuit.

4. The electronic still camera of claim 1 wherein the motion processing means and the still processing means produce the second number of pixels and the third number of pixels, respectively, prior to transferring the image pixels to the display and the digital memory, respectively.

5. The electronic still camera of claim 1 wherein the second number of pixel values representative of the series of motion images are transferred to the display in a digital format.

6. The electronic still camera of claim 1 wherein the second number of pixel values representative of the series of motion images are mapped into a form suitable for display.

7. The electronic still camera of claim 6 wherein after the second number of pixel values representative of the series of motion images are mapped into a form suitable for display, the signals representing the captured images are converted back into an analog form.

8. The electronic still camera of claim 1 further including a firmware memory, a processor, and an application specific integrated circuit, and wherein the first processing means is provided in the application specific integrated circuit, and the second processing means is provided using the processor which implements software procedures stored in the firmware memory.

9. The electronic still camera of claim 1 wherein the image sensor includes a color filter array to produce color image data, the second processing means processes the color image data and performs JPEG image compression on the captured still image, and the JPEG compressed still image is stored in the digital memory.

10. The electronic still camera of claim 9 wherein the digital memory is a removable memory card.

11. The electronic still camera of claim 1 wherein the first color pattern includes substantially one-half green color filters.

12. The electronic still camera of claim 11 wherein the color display pixels are arranged in a pattern having substantially one-third green color filters.

13. The electronic still camera of claim 1 wherein the first color pattern is a Bayer checkerboard pattern.

14. The electronic still camera of claim 1 wherein the distance between adjacent image sensor photosites in the horizontal direction are substantially equal to the distance between the adjacent image sensor photosites in the vertical direction, and wherein the distance between the adjacent color display pixels in the horizontal direction is different than the distance between the adjacent color display pixels in the vertical direction.

15. An electronic still camera for initiating capture of a still image while previewing motion images on a display, comprising:

- (a) an image sensor having a two-dimensional array of photosites covered by a mosaic pattern of color filters including at least three different colors for capturing images of a scene, each captured image having a first number of color pixel values provided in a first color pattern;
- (b) a motion processor for generating from the captured images, a second number of color pixel values provided in a second color pattern having at least three different colors and representative of a series of motion images to be previewed, the second number of color pixel values being less than the first number of color pixel values, and the second color pattern being different from the first color pattern;
- (c) a color display for presenting at least some of the motion images of the series of motion images corresponding to the captured images of the scene, the color display having an arrangement of color display pixels including at least three different colors in a pattern different from the first color pattern;
- (d) a capture button for initiating capture of a still image while previewing the motion images presented on the color display;
- (e) a still processor for generating a third number of color pixel values including at least three different colors representative of a captured still image; and

13

(f) a digital memory for storing the processed captured still image.

16. The electronic still camera of claim 15 further including a multiplexer having first and second inputs and an output, wherein the first input is coupled to the first processor, the second input is coupled to the second processor, and the output is coupled to the display so that a captured still image can be viewed on the display.

17. The electronic still camera of claim 15 wherein the first processor and the second processor are integrated into a single integrated circuit.

18. The electronic still camera of claim 15 wherein the motion processor and the still processor produce the second number of pixels and the third number of pixels, respectively, prior to transferring the image pixels to the display and the digital memory, respectively.

19. The electronic still camera of claim 15 wherein the second number of pixel values representative of the series of motion images are transferred to the display in a digital format.

20. The electronic still camera of claim 15 wherein the second number of pixel values representative of the series of motion images are mapped into a form suitable for display.

21. The electronic still camera of claim 20 wherein after the second number of pixel values representative of the series of motion images are mapped into a form suitable for display, the signals representing the captured images are converted back into an analog form.

22. The electronic still camera of claim 15 further including a firmware memory, and an application specific inte-

14

grated circuit, and wherein the first processor is provided in the application specific integrated circuit, and the second processor implements software procedures stored in the firmware memory.

23. The electronic still camera of claim 15 wherein the image sensor includes a color filter array to produce color image data, the second processor processes the color image data and performs JPEG image compression on the captured still image, and the JPEG compressed still image is stored in the digital memory.

24. The electronic still camera of claim 23 wherein the digital memory is a removable memory card.

25. The electronic still camera of claim 15 wherein the first color pattern includes substantially one-half green color filters.

26. The electronic still camera of claim 25 wherein the color display pixels are arranged in a pattern having substantially one-third green color filters.

27. The electronic still camera of claim 15 wherein the first color pattern is a Bayer checkerboard pattern.

28. The electronic still camera of claim 15 wherein the distance between adjacent image sensor photosites in the horizontal direction are substantially equal to the distance between the adjacent image sensor photosites in the vertical direction, and wherein the distance between the adjacent color display pixels in the horizontal direction is different than the distance between the adjacent color display pixels in the vertical direction.

(57) **ABSTRACT**

A network configuration file is generated at a host computer and downloaded to a digital camera. This file contains instruction information for communicating with a selected destination via a communications interface. The digital camera includes a “send” button or LCD icon which allows the user to easily transmit one or more images via a wired or wireless communications interface to a desired destination, which among other possibilities may be an Internet Service Provider or a digital photofinishing center. When the user selects this option, the communications port settings, user account specifics, and destination connection commands are read from the network configuration file on the removable memory card. Examples of these settings include serial port baud rate, parity, and stop bits, as well as account name and password.

AUTOMATICALLY TRANSMITTING IMAGES FROM AN ELECTRONIC CAMERA TO A SERVICE PROVIDER USING A NETWORK CONFIGURATION FILE

CROSS REFERENCE TO RELATED APPLICATION

Reference is made to and priority claimed from U.S. Provisional Application Ser. No. 60/037,962, filed Feb. 20, 1997, entitled NETWORK CONFIGURATION FILE FOR AUTOMATICALLY TRANSMITTING IMAGES FROM AN ELECTRONIC STILL CAMERA.

CROSS-REFERENCE TO RELATED APPLICATION(S)

This is a continuation of application Ser. No. 09/004,046 filed Jan. 7, 1998 now U.S. Pat. No. 6,784,924 entitled "Network Configuration File For Automatically Transmitting Images From An Electronic Still Camera".

FIELD OF THE INVENTION

The invention relates generally to the field of photography, and in particular to electronic photography. More specifically, the invention relates to a digital camera that interfaces with a host computer.

BACKGROUND OF THE INVENTION

Digital cameras, such as the Kodak Digital Science DC25™ camera, allow images to be utilized on a home computer (PC) and to be incorporated into e-mail documents and personal home pages on the World Wide Web. Presently, images must be copied to the PC and transmitted as e-mail, for example using an online service or an Internet Service Provider (ISP), via a modem from the user's PC. It would be desirable to be able to transmit pictures directly from the digital camera instead of first transferring the pictures to a PC. For instance, on a vacation trip, it is desirable to immediately share pictures with friends or relatives via e-mail or Internet access. It is also desirable to transmit pictures from a location without PC access in order to free up camera storage to take additional pictures. There are a wide variety of connection means to online services such as America On Line, ISPs, and bulletin board services. Each of these services typically requires an account name and password, as well as local telephone access numbers, and specific communications settings. It would be difficult to provide an easy-to-use means with buttons or menus on a small digital camera to input and/or modify all of these required settings.

SUMMARY OF THE INVENTION

The present invention is directed to overcoming one or more of the problems set forth above. Briefly summarized, according to one aspect of the present invention, a network configuration file is generated at a host computer and downloaded to a digital camera. This file contains instruction information for communicating with a selected destination via a communications interface. The digital camera includes a "send" button or LCD icon which allows the user to easily transmit one or more images via a wired or wireless communications interface to a desired destination, which among other possibilities may be an Internet Service Pro-

2

vider or a digital photofinishing center. When the user selects this option, the communications port settings, user account specifics, and destination connection commands are read from the network configuration file. Examples of these settings include serial port baud rate, parity, and stop bits, as well as account name and password.

In addition, information about which image or images to transmit is entered using the user buttons on the digital camera. This information is used to automatically establish a connection, log-in to the desired destination, and to transmit the image. The transmission may occur immediately after the pictures are taken, for example if the camera has a built-in cellular phone modem, or at a later time, when the camera is connected to a separate unit (such as a dock, kiosk, PC, etc.) equipped with a modem. In the latter case, a "utilization file" is created to provide information on which images should be transmitted to which account.

These and other aspects, objects, features and advantages of the present invention will be more clearly understood and appreciated from a review of the following detailed description of the preferred embodiments and appended claims, and by reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a system block diagram of the invention.

FIG. 2 is a diagram showing the steps used to automatically transmit images using the network configuration file.

FIG. 3 is a diagram of an image file.

FIG. 4 is a diagram showing several versions of the network configuration file.

DETAILED DESCRIPTION OF THE INVENTION

Because imaging systems and devices are well known, the present description will be directed in particular to elements forming part of, or cooperating more directly with, apparatus in accordance with the present invention. Elements not specifically shown or described herein may be selected from those known in the art. Some aspects of the present description may be implemented in software. Unless otherwise specified, all software implementation is conventional and within the ordinary skill in the programming arts.

A system block diagram of the invention is shown in FIG. 1 including an electronic still camera 10, a host computer (PC) 12 and a service provider 14. The camera includes an optical section 20 for imaging a scene upon a CCD sensor 22 and generating an image signal, a liquid crystal display (LCD) 24 for displaying images and other information, a number of user input buttons 26, both permanent memory 28 and removable memory 30, and an internal communications interface 32 (e.g., modem). This interface may connect to a variety of known networks, such as a public switched telephone network (PSTN), ISDN, an RF cellular phone network, or Ethernet. The camera 10 also includes a micro-processor 34 for generally controlling the camera functions, as well as the interchange of data with the host PC 12 and the memory card 30 through a host PC interface 36 and a memory card interface 38, respectively. Besides the host PC 12, the system includes a network connection 40 to the online service or ISP (Internet Service Provider) 14. Alternately, the network 40 can connect to the user's home PC 12.

When the camera 10 is first purchased (or at any time thereafter), it is connected to the PC 12 via the host PC 36 interface and a software application (stored on a disc 45) running on the host PC 12 will enable the user to specify the

3

name of a destination ISP or online service and to input from the host PC keyboard 44 the appropriate communication settings and account information. This information generates a network configuration file, which then can then be downloaded to the camera 10 through the host PC interface 36, which may be a wired or infrared (e.g., IrDA) interface, and written to the camera's internal memory 28 and/or the removable memory card 30. Alternatively, a host PC equipped with a memory card reader/writer 42 can write the information directly to the card 30 without connecting the camera through its host PC interface 36. Also, this information could be predetermined by the user and stored in a "preferences" file on the host PC 12 and then transferred to the camera 10 from this file without further intervention by the user. Multiple sets of destination services can be stored on the memory card 30. Typically, keyword or graphic descriptors (e.g., icons) accompany the information in the network configuration file about destination services to enable easy access by the camera user.

The steps used to automatically transmit images using the network configuration file are shown in FIG. 2. After disconnecting the camera from the host PC, the user operates the camera to take pictures (step 50). This is typically done at a remote location, for example while traveling to another city. As the user takes or reviews images on the image LCD display, the decision can be made to transmit one or more images (step 52). This is done by choosing one of the keywords or icons in a menu 54 shown in FIG. 2, which are displayed on the LCD 24 and selected, e.g., through the user buttons 26. (Note that a camera will typically only include a subset (only those desired by the user) of all the different services shown.) The selected image files may be tagged with a code (step 56) indicating which service is requested, as shown in FIG. 3. (Alternately, an "image utilization" file can be created in the camera storing a list of images to be transmitted by a particular method, as described in the cross-referenced copending patent application (U.S. Ser. No. 60/037,963). As described in that patent application, the details of an order, e.g., number of print copies to be made from an image and the size of the prints and/or a list of images to be e-mailed to various recipients, is written into the "utilization" file, which identifies the order and includes pointers to the image files that store the images required to "fulfill" the order. The "utilization" file is stored in the internal memory 28 or the memory card 30.)

Next, the system determines whether a request exists to send an image (step 58). If no request is present, the image and associated data is stored in either permanent memory 28 or the memory card 30 (step 59). (Typically, all images are initially saved in memory whether eventually sent or not.) Otherwise, if there is a request to send an image, the user ensures that the camera is connected to the appropriate service (wired telephone line, cellular phone, kiosk, etc.) and pushes a "send" button in the user button section 26, or selects a "send" menu option on the LCD 24. The camera then utilizes the appropriate network configuration file, shown in FIG. 4. Each network configuration file contains items such as the protocol type, phone number, etc., as described in Appendix I. The user password may be checked against the password in the network configuration file to ensure that the user is authorized to connect the camera to the desired service (step 60). Alternately, the stored password in the appropriate configuration file can be used. Next, the camera uses the parameters in the configuration file to establish communications with the service and send one or more image files as selected by the user (steps 62). The service receiver interprets the system commands issued by

4

the camera from the network configuration file list and sends appropriate feedback (such as "transfer in progress" and "transfer complete") which are interpreted by the camera and displayed on the LCD 24 (steps 64).

For example, when the camera uses a normal wired telephone (Public Switched Telephone Network) connection (i.e., network 40) to the camera's internal modem 32, after the user selects the images to be sent and presses the "send" button, the camera performs the following steps without user intervention:

- 1) Read the appropriate connection parameters from the network configuration file (on the memory card 30 or internal camera memory 28), dial the phone and establish the connection to the destination service 14.
- 2) Read the user's account name and password and transmit these to "log-on" to the service 14.
- 3) Using the appropriate communications protocol (FTP, mailto, etc.), transmit the selected image or images to the destination service 14.

The invention has been described with reference to a preferred embodiment. However, it will be appreciated that variations and modifications can be effected by a person of ordinary skill in the art without departing from the scope of the invention.

APPENDIX I

These are descriptions of the tags listed in the previous drawing:

Protocol Type

Each communication method has its own protocol, or rules to communicate. This tag identifies that protocol and where to find it. For example, the Network may use TCP/IP and a modem may use XModem.

Phone Number

This is the number of the receiving service. If internet access is requested, this could be the number of the Internet Service Provider. For ISDN, some systems require two phone numbers, dialed and connected to in sequence.

Default Settings

Standard settings that make the communications device compatible with the imaging device.

Modem Control String

Modem and communications devices have a command language that can set them up before they are used. For example, modems have many options controlled by command strings including volume level, the amount of time the carrier is allowed to fail before the system hangs up, and so on.

Account Data

This can be internet account data, charge number data, phone card data, billing address, and data related to the commerce part of the transmission.

Password

Any password needed to get into the communications system. Other passwords to get into the remote application or destination are located in the System Commands section.

System Commands

These are commands that control the end destination.

Error Protocol

In cellular and some other wireless communications, error protocols are used to increase the robustness of the link. For example, MNP10 or ETC may be used for cellular links.

Radio Type

The type of radio used for this communications feature may be identified here. Some cell phones have modems built in, others will have protocols for many communications functions built in. The radio type will make the imaging device adapt to the correct interface.

IOC

ISDN Ordering Code identifies what features are available on the ISDN line provided by the teleco. It is used to establish the feature set for that communications link.

Internet Service Provider

This identifies the actual service provider and any specific information or sequence of information that the service wants to see during connection and logoff. It also tells the device how to handle the return messages, like "time used" that are returned by the server.

Commands to Receiver

This may be a list of commands to control the receiving application. For example, a command to print one of the images and save the data to a particular file on a PC may be embedded here.

Return Status Requests

This tag can set up the ability of the application to tell if an error has occurred, or what the status of the application might be. The data here will help the device decide if it should continue communicating and a set user interface response can be developed around this feedback.

What is claimed is:

1. A method of transferring one of more images from an electronic camera to a service provider, the camera including optics and an image sensor for generating an image signal, a display for displaying images, a plurality of user inputs, a first digital memory for storing digital images, a second digital memory for storing a network configuration file, and a communications interface, the method comprising the steps of:

- (a) storing the network configuration file for the service provider in the second digital memory;
- (b) subsequently using the optics and image sensor to generate a plurality of image signals which are stored as a plurality of digital images in the first digital memory;
- (c) viewing at least one of the plurality of digital images on the display of the electronic camera;
- (d) using at least one of the plurality of user inputs to select at least one digital image for transfer to the service provider;
- (e) using at least one of the plurality of user inputs to initiate transfer of the selected at least one digital image to the service provider;
- (f) using the network configuration file, the electronic camera automatically establishing communications with the service provider and transferring the selected digital image(s) from the electronic camera to the service provider using the communications interface;
- (g) transferring from the service provider to the electronic camera, feedback indicating the status of the transfer process; and
- (h) displaying the status on the display of the electronic camera.

2. The method as claimed in claim 1 wherein the network configuration file includes a protocol type identifier.

3. The method as claimed in claim 2 wherein protocol type identifier identifies a TCP/IP protocol.

4. The method as claimed in claim 1 wherein the network configuration file includes account data.

5. A method of transferring one or more digital images from an electronic camera to a service, the camera including optics and an image sensor for generating an image signal, a display for displaying images, a plurality of user inputs, a first digital memory for storing digital images, a second digital memory for storing a network configuration file, and a communications interface, the method comprising:

- (a) storing the network configuration file for the service in the second digital memory, wherein the network configuration file includes a protocol type identifier identifying a TCP/IP protocol;
- (b) subsequently using the optics and image sensor to generate a plurality of image signals which are stored in the first digital memory as a plurality of digital images representative of the plurality of image signals;
- (c) displaying a representation of at least one of the plurality of digital images on the display of the electronic camera;
- (d) selecting at least one digital image for transfer to the service in response to the use of at least one of the plurality of user inputs;
- (e) initiating transfer of the selected at least one digital image to the service in response to use of at least one of the plurality of user inputs; and
- (f) using the network configuration file to automatically establish communications with the service and to transfer the selected at least one digital image from the electronic camera to the service using the communications interface.

6. The method of claim 5 further including:

- (g) receiving feedback indicating the status of the transfer process from the service; and
- (h) displaying the status on the display of the electronic camera.

7. The method of claim 5 wherein the network configuration file includes account data.

8. The method of claim 5 wherein the network configuration file is generated at least in part by a host device.

9. A method of transferring one or more digital images from an electronic camera to a service, the camera including optics and an image sensor for generating an image signal, a display for displaying images, a plurality of user inputs, a first digital memory for storing digital images, a second digital memory for storing a network configuration file, and a communications interface, the method comprising:

- (a) storing the network configuration file for the service in the second digital memory;
- (b) subsequently using the optics and image sensor to generate a plurality of image signals which are stored in the first digital memory as a plurality of digital images representative of the plurality of image signals;
- (c) displaying a representation of at least one of the plurality of digital images on the display of the electronic camera;
- (d) selecting at least one digital image for transfer to the service in response to the use of at least one of the plurality of user inputs;
- (e) initiating transfer of the selected at least one digital image to the service in response to use of at least one of the plurality of user inputs;
- (f) using the network configuration file to automatically establish communications with the service and to transfer the selected at least one digital image from the

7

electronic camera to the service using the communications interface;
(g) receiving information indicating the status of the transferring at least one digital image from the electronic camera to the service; and
(h) displaying an indication of the status.

8

10. The method of claim **9** wherein the network configuration file includes account data.

11. The method of claim **10** wherein the network configuration file is generated at least in part by a host device.

NETWORK CONFIGURATION FILE FOR AUTOMATICALLY TRANSMITTING IMAGES FROM AN ELECTRONIC STILL CAMERA

CROSS-REFERENCE TO RELATED APPLICATION(S)

This is a continuation of U.S. Ser. No. 09/783,437 filed Feb. 14, 2001 (which issued as U.S. Pat. No. 7,256,823 on Aug. 14, 2007, which is now Reissue application Ser. No. 12/540,610) which is a divisional of U.S. Ser. No. 09/004,046 filed Jan. 7, 1998 (now U.S. Pat. No. 6,784,924 which issued on Aug. 31, 2004) which claims the benefit of U.S. Provisional Application No. 60/037,962 filed Feb. 20, 1997.

FIELD OF THE INVENTION

The invention relates generally to the field of photography, and in particular to electronic photography. More specifically, the invention relates to a digital camera that interfaces with a host computer.

BACKGROUND OF THE INVENTION

Digital cameras, such as the Kodak Digital Science DC25™ camera, allow images to be utilized on a home computer (PC) and to be incorporated into e-mail documents and personal home pages on the World Wide Web. Presently, images must be copied to the PC and transmitted as e-mail, for example using an online service or an Internet Service Provider (ISP), via a modem from the user's PC. It would be desirable to be able to transmit pictures directly from the digital camera instead of first transferring the pictures to a PC. For instance, on a vacation trip, it is desirable to immediately share pictures with friends or relatives via e-mail or Internet access. It is also desirable to transmit pictures from a location without PC access in order to free up camera storage to take additional pictures. There are a wide variety of connection means to online services such as America On Line, ISPs, and bulletin board services. Each of these services typically requires an account name and password, as well as local telephone access numbers, and specific communications settings. It would be difficult to provide an easy-to-use means with buttons or menus on a small digital camera to input and/or modify all of these required settings.

SUMMARY OF THE INVENTION

The present invention is directed to overcoming one or more of the problems set forth above. Briefly summarized, according to one aspect of the present invention, a network configuration file is generated at a host computer and downloaded to a digital camera. This file contains instruction information for communicating with a selected destination via a communications interface. The digital camera includes a "send" button or LCD icon which allows the user to easily transmit one or more images via a wired or wireless communications interface to a desired destination, which among other possibilities may be an Internet Service Provider or a digital photofinishing center. When the user selects this option, the communications port settings, user account specifics, and destination connection commands are read from the network configuration file. Examples of these settings include serial port baud rate, parity, and stop bits, as well as account name and password.

In addition, information about which image or images to transmit is entered using the user buttons on the digital cam-

2

era. This information is used to automatically establish a connection, log-in to the desired destination, and to transmit the image. The transmission may occur immediately after the pictures are taken, for example if the camera has a built-in cellular phone modem, or at a later time, when the camera is connected to a separate unit (such as a dock, kiosk, PC, etc.) equipped with a modem. In the latter case, a "utilization file" is created to provide information on which images should be transmitted to which account.

These and other aspects, objects, features and advantages of the present invention will be more clearly understood and appreciated from a review of the following detailed description of the preferred embodiments and appended claims, and by reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a system block diagram of the invention.

FIG. 2 is a diagram showing the steps used to automatically transmit images using the network configuration file.

FIG. 3 is a diagram of an image file.

FIG. 4 is a diagram showing several versions of the network configuration file.

DETAILED DESCRIPTION OF THE INVENTION

Because imaging systems and devices are well known, the present description will be directed in particular to elements forming part of, or cooperating more directly with, apparatus in accordance with the present invention. Elements not specifically shown or described herein may be selected from those known in the art. Some aspects of the present description may be implemented in software. Unless otherwise specified, all software implementation is conventional and within the ordinary skill in the programming arts.

A system block diagram of the invention is shown in FIG. 1 including an electronic still camera 10, a host computer (PC) 12 and a service provider 14. The camera includes an optical section 20 for imaging a scene upon a CCD sensor 22 and generating an image signal, a liquid crystal display (LCD) 24 for displaying images and other information, a number of user input buttons 26, both permanent memory 28 and removable memory 30, and an internal communications interface 32 (e.g., modem). This interface may connect to a variety of known networks, such as a public switched telephone network (PSTN), ISDN, an RF cellular phone network, or Ethernet. The camera 10 also includes a microprocessor 34 for generally controlling the camera functions, as well as the interchange of data with the host PC 12 and the memory card 30 through a host PC interface 36 and a memory card interface 38, respectively. Besides the host PC 12, the system includes a network connection 40 to the online service or ISP (Internet Service Provider) 14. Alternately, the network 40 can connect to the user's home PC 12.

When the camera 10 is first purchased (or at any time thereafter), it is connected to the PC 12 via the host PC 36 interface and a software application (stored on a disc 45) running on the host PC 12 will enable the user to specify the name of a destination ISP or online service and to input from the host PC keyboard 44 the appropriate communication settings and account information. This information generates a network configuration file, which then can then be downloaded to the camera 10 through the host PC interface 36, which may be a wired or infrared (e.g., IrDA) interface, and written to the camera's internal memory 28 and/or the removable memory card 30. Alternatively, a host PC equipped with a memory card reader/writer 42 can write the information

3

directly to the card **30** without connecting the camera through its host PC interface **36**. Also, this information could be predetermined by the user and stored in a "preferences" file on the host PC **12** and then transferred to the camera **10** from this file without further intervention by the user. Multiple sets of destination services can be stored on the memory card **30**. Typically, keyword or graphic descriptors (e.g., icons) accompany the information in the network configuration file about destination services to enable easy access by the camera user.

The steps used to automatically transmit images using the network configuration file are shown in FIG. 2. After disconnecting the camera from the host PC, the user operates the camera to take pictures (step **50**). This is typically done at a remote location, for example while traveling to another city. As the user takes or reviews images on the image LCD display, the decision can be made to transmit one or more images (step **52**). This is done by choosing one of the keywords or icons in a menu **54** shown in FIG. 2, which are displayed on the LCD **24** and selected, e.g., through the user buttons **26**. (Note that a camera will typically only include a subset (only those desired by the user) of all the different services shown.) The selected image files may be tagged with a code (step **56**) indicating which service is requested, as shown in FIG. 3. (Alternately, an "image utilization" file can be created in the camera storing a list of images to be transmitted by a particular method, as described in the cross-referenced copending patent application (U.S. Ser. No. 60/037,963). As described in that patent application, the details of an order, e.g., number of print copies to be made from an image and the size of the prints and/or a list of images to be e-mailed to various recipients, is written into the "utilization" file, which identifies the order and includes pointers to the image files that store the images required to "fulfill" the order. The "utilization" file is stored in the internal memory **28** or the memory card **30**.)

Next, the system determines whether a request exists to send an image (step **58**). If no request is present, the image and associated data is stored in either permanent memory **28** or the memory card **30** (step **59**). (Typically, all images are initially saved in memory whether eventually sent or not.) Otherwise, if there is a request to send an image, the user ensures that the camera is connected to the appropriate service (wired telephone line, cellular phone, kiosk, etc.) and pushes a "send" button in the user button section **26**, or selects a "send" menu option on the LCD **24**. The camera then utilizes the appropriate network configuration file, shown in FIG. 4. Each network configuration file contains items such as the protocol type, phone number, etc., as described in Appendix I. The user password may be checked against the password in the network configuration file to ensure that the user is authorized to connect the camera to the desired service (step **60**). Alternately, the stored password in the appropriate configuration file can be used. Next, the camera uses the parameters in the configuration file to establish communications with the service and send one or more image files as selected by the user (steps **62**). The service receiver interprets the system commands issued by the camera from the network configuration file list and sends appropriate feedback (such as "transfer in progress" and "transfer complete") which are interpreted by the camera and displayed on the LCD **24** (steps **64**).

For example, when the camera uses a normal wired telephone (Public Switched Telephone Network) connection (i.e., network **40**) to the camera's internal modem **32**, after the user selects the images to be sent and presses the "send" button, the camera performs the following steps without user intervention:

4

- 1) Read the appropriate connection parameters from the network configuration file (on the memory card **30** or internal camera memory **28**), dial the phone and establish the connection to the destination service **14**.
- 2) Read the user's account name and password and transmit these to "log-on" to the service **14**.
- 3) Using the appropriate communications protocol (FTP, mailto, etc.), transmit the selected image or images to the destination service **14**.

The invention has been described with reference to a preferred embodiment. However, it will be appreciated that variations and modifications can be effected by a person of ordinary skill in the art without departing from the scope of the invention.

APPENDIX I

These are descriptions of the tags listed in the previous drawing:

Protocol Type

Each communication method has its own protocol, or rules to communicate. This tag identifies that protocol and where to find it. For example, the Network may use TCP/IP and a modem may use XModem.

Phone Number

This is the number of the receiving service. If internet access is requested, this could be the number of the Internet Service Provider. For ISDN, some systems require two phone numbers, dialed and connected to in sequence.

Default Settings

Standard settings that make the communications device compatible with the imaging device.

Modem Control String

Modem and communications devices have a command language that can set them up before they are used. For example, modems have many options controlled by command strings including volume level, the amount of time the carrier is allowed to fail before the system hangs up, and so on.

Account Data

This can be internet account data, charge number data, phone card data, billing address, and data related to the commerce part of the transmission.

Password

Any password needed to get into the communications system. Other passwords to get into the remote application or destination are located in the System Commands section.

System Commands

These are commands that control the end destination.

Error Protocol

In cellular and some other wireless communications, error protocols are used to increase the robustness of the link. For example, MNP **10** or ETC may be used for cellular links.

Radio Type

The type of radio used for this communications feature may be identified here. Some cell phones have modems built in, others will have protocols for many communications functions built in. The radio type will make the imaging device adapt to the correct interface.

5

IOC

ISDN Ordering Code identifies what features are available on the ISDN line provided by the teleco. It is used to establish the feature set for that communications link.

Internet Service Provider

This identifies the actual service provider and any specific information or sequence of information that the service wants to see during connection and logoff. It also tells the device how to handle the return messages, like "time used" that are returned by the server.

Commands to Receiver

This may be a list of commands to control the receiving application. For example, a command to print one of the images and save the data to a particular file on a PC may be embedded here.

Return Status Requests

This tag can set up the ability of the application to tell if an error has occurred, or what the status of the application might be. The data here will help the device decide if it should continue communicating and a set user interface response can be developed around this feedback.

What is claimed is:

1. An electronic camera comprising:

a communication interface;

a sensor for capturing images;

a first memory for storing images;

a second memory for storing information for communicating with a plurality of destinations via the communications interface; and

a user interface for selecting an image destination and for commanding the camera to send the images to the

6

selected destination via the communications interface using the information, and wherein the user interface displays a plurality of descriptive icons representative of the plurality of destinations and selection is made by reference to at least one of the icons.

2. The camera of claim 1, wherein both first and second memories are memory locations on the same removable memory card.

3. The camera of claim 1, wherein the second memory permanently resides in the camera and can be loaded with a network configuration file from a host PC.

4. The camera of claim 3, wherein the network configuration file further includes information to enable connection to an identified Internet Service Provider.

5. The camera of claim 1, wherein the communications interface connects to PSTN (Public Switched Telephone Network).

6. The camera of claim 1, wherein the communications interface connects to ISDN.

7. The camera of claim 1, wherein the communications interface connects to an RF cellular phone network.

8. The camera of claim 1, wherein the communications interface connects to a data network.

9. The camera of claim 8, wherein the data network is an Ethernet.

10. The camera of claim 1, wherein the communications interface is located internal to the camera.

11. The camera of claim 1, wherein the user interface displays a feedback indicating the status of the image transfer.

(57) **ABSTRACT**

An electronic still camera for capturing images to be trans-
ferred to at least one e-mail address is disclosed. The elec-
tronic still camera includes an image sensor for capturing a
plurality of images of scenes and for producing image signals
representative of the corresponding scenes; an analog-to-
digital converter for digitizing the image signals to produce
digital images; and a removable memory card for storing a
plurality of digital image files corresponding to the digital
images. The electronic still camera also includes an internal
memory for storing at least one digital image to be displayed
and a plurality of e-mail addresses; a processor for controlling
the transfer of the digital images from the removable memory
card to the internal memory and for producing a utilization
file; and a display coupled to the internal memory for display-
ing at least one digital image. The electronic still camera
further includes a user interface for selecting at least one
e-mail address and for scrolling through the plurality of digi-
tal images stored on the removable memory card in order to
display and select particular digital images to be transferred
to the selected at least one e-mail address, wherein the utili-
zation file includes the at least one selected e-mail address and
the name of at least one digital image file to be transferred to
the at least one selected e-mail address and the processor
stores the utilization file on the removable memory card sepa-
rate from the digital image files.

CAPTURING DIGITAL IMAGES TO BE TRANSFERRED TO AN E-MAIL ADDRESS

CROSS-REFERENCE TO RELATED APPLICATION(S)

This application is a Continuation Application of U.S. Ser. No. 09/821,152, filed Mar. 29, 2001 now U.S. Pat. No. 7,034,871, by Kenneth A. Parulski et al., entitled Electronic Still Camera for Capturing Digital Images to be Transferred to an E-Mail Address, which is a Continuation of U.S. Ser. No. 08/977,382, filed Nov. 24, 1997 now issued as U.S. Pat. No. 6,573,927 on Jun. 3, 2003.

FIELD OF THE INVENTION

The invention relates generally to the field of photography, and in particular to electronic photography. More specifically, the invention relates to an electronic camera that can be interfaced with a host computer.

BACKGROUND OF THE INVENTION

Digital cameras, such as the Kodak Digital Science DC25™ camera, allow images to be utilized on a home computer (PC) and to be incorporated into e-mail documents and personal home pages on the World Wide Web. Presently, if a print is desired, each image must first be copied to the PC and then individually printed. The user is required to manually select each image to be printed, and manually decide how big each print should be and how many prints to make of each image.

In addition, it is possible for users to electronically send images to others using software, such as the Kodak Digital Science Picture Postcard Software™. However, this again requires the user to manually download each image to the host computer, select each image to be transmitted, and create a new "Postcard" for each image to be sent. Users can also create "albums" of photos on their computers using software such as the Family Album Creator™ by Creative Wonders, Inc. Again, however, this is a manual process that requires each image to be downloaded to the computer, individually selected, and added to the album.

In U.S. Pat. No. 5,241,659, reprint information can be generated at the time a PhotoCD disc is played back. This patent describes an EEPROM card that can be inserted into a PhotoCD player. As shown in FIGS. 3, 5, and 6 of this patent, the EEPROM card can contain reprint order information and "album disc" information input by the player operator. However, this information is not generated at the time of picture taking, and is not stored on the same media as the images. Moreover, the reprint information does not include information useful to the service provider, such as user account, charge card, and mailing address.

What is needed is a way for camera users to quickly and easily compose "print orders" and "transmission orders" and/or "electronic albuming" orders, at the time they capture their images.

SUMMARY OF THE INVENTION

Accordingly, it is an object of the present invention to provide an electronic still camera for capturing images to be transferred to at least one e-mail address, the electronic still camera comprising:

- (a) an image sensor for capturing a plurality of images of scenes and for producing image signals representative of the corresponding scenes;

2

- (b) an analog-to-digital converter for digitizing the image signals to produce digital images;
- (c) a removable memory card for storing a plurality of digital image files corresponding to the digital images;
- (d) an internal memory for storing at least one digital image to be displayed and a plurality of e-mail addresses;
- (e) a processor for controlling the transfer of the digital images from the removable memory card to the internal memory and for producing a utilization file;
- (f) a display coupled to the internal memory for displaying at least one digital image; and
- (g) a user interface for selecting at least one e-mail address and for scrolling through the plurality of digital images stored on the removable memory card in order to display and select particular digital images to be transferred to the selected at least one e-mail address, wherein the utilization file includes the at least one selected e-mail address and the name of at least one digital image file to be transferred to the at least one selected e-mail address and the processor stores the utilization file on the removable memory card separate from the digital image files.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of the system according to the invention;

FIG. 2 is a diagram of downstream services available in the system shown in FIG. 1;

FIG. 3 is an illustration of one example of a creative background added to an image;

FIG. 4 is a diagram of the organization of a utilization file; and

FIG. 5 is a diagram of another organization of a utilization file together with each image file.

DETAILED DESCRIPTION OF THE INVENTION

Because imaging systems and devices are well known, the present description will be directed in particular to elements forming part of, or cooperating more directly with, apparatus in accordance with the present invention. Elements not specifically shown or described herein may be selected from those known in the art. Some aspects of the present description may be implemented in software. Unless otherwise specified, all software implementation is conventional and within the ordinary skill in the programming arts.

A system block diagram of the invention is shown in FIG. 1, and includes a user's host computer (PC) 10, a digital camera 12, equipment located at a "downstream" service provider 14, and equipment at a walk-up kiosk 16. The camera 12 includes an optical section 18 for imaging a scene upon an image sensor 20 and generating an image signal, an A/D converter 22 for digitizing the image signal, a liquid crystal display (LCD screen) 24 for displaying images and other information, a number of user input buttons 26, and both internal memory 32 and a removable memory card 36 for storing captured images. The camera 12 may optionally include an internal communications interface 28 (e.g., modem). A microprocessor 29 generally controls the operation of the camera 12, and interchanges data through a memory card interface 34 with the memory card 36, through a PC interface 38 with the host computer 10, through a host interface 30 directly with the kiosk 16, and through the communications interface 28 and a communications network 31 with the service provider 14.

When the camera 12 is purchased, it is provided with a software application (located on a disc 40) for running on the

3

user's host PC 10 that enables the user to specify the name(s) of downstream service providers, network addresses (friends, family or business associates) and related account information such as billing information (e.g., charge card number, mailing addresses). The user can also select, through the software application, one or more "creative backgrounds" offered by the service provider (such as a postcard border) and enter one or more text messages, (such as "Hi, I'm having a relaxing vacation, John Smith"), as will be described in connection with FIG. 3. All of this information can then be downloaded, via a memory card reader 42 on the host PC 10, to the removable memory card 36, which can be subsequently inserted into the camera 12. Alternatively, the information can be downloaded to the camera 12 via the host PC interface 38 and written to the camera's internal memory 32 or the removable memory card 36 in the camera. Typically, keyword descriptors accompany the information to enable easy access by the camera user.

After placing the memory card 36 in the camera 12 (or disconnecting the camera 12 from the host PC 10), the user can operate the camera 12 to take numerous pictures, which are stored either in the internal memory 32 or in the memory card 36 (or in both). After taking pictures, the user reviews the images on the LCD screen 24, using the buttons 26 to scroll through the images. The user can then select the desired "downstream services" (printing, e-mailing, and/or albuming) and compose the order using the options listed in FIG. 2. These services and options are accessed from the memory card 36 and, for example, the keyword descriptors are assembled in a menu and displayed on the LCD screen 24. Selections among these services and options are made, for example, by reference to the keyword descriptors and actuation of the user buttons 26. The details of the order information is written into a "utilization" file generated by the camera 12 that identifies the order and includes pointers to the image files that store the images required to "fulfill" the order. The "utilization" file is stored in the internal memory 32 or the memory card 36.

For printing, order composition involves selecting the quantity, print size, and quality level (e.g., thermal or ink jet) of the images to be printed. For example, the user might choose one "standard" (4"×6" size) image of 2 different images, and 2 standard size images plus one "enlargement" (8"×10" size) image of their "favorite" vacation image. The print order information is provided in the utilization file that identifies the order and includes pointers to the image files that store the images required to "fulfill" the print order. In addition to "normal" type prints, the prints can be "creative" prints, using one of the creative backgrounds selected on the host computer and downloaded to the camera along with text. In this case, the "favorite" image might be surrounded with one of the border and captions provided via the host PC 10, as shown in FIG. 3.

The user can then take or mail the image memory card 36 containing the image files and order information (utilization file) to the print service provider 14. The provider reads the information, fills the print order, and returns the print order either for pick-up by the user or by mail. The service provider 14 charges the user's credit card account (which can be stored in the print order information file) for the prints provided. Alternatively, the user can place the card 36 in a slot 50 of a "walk-up kiosk" 16 along with a credit card. The kiosk can then automatically produce the prints required while minimizing the amount of user interaction required. Finally, the user could place the card in a home printer 48, and the printer could automatically produce the quantity of prints of each image required. In the last two cases, the size and quality of

4

print types available might be limited to those available by the kiosk 16 or the home printer 48.

Alternatively, the camera 12 could incorporate or be connected to a wired or wireless modem, such as the communications interface 28. In this case, the print order information, and the image information needed to fulfill the print order, would be transmitted to the service provider 14 along with the account information through the communication network 31 (which could be a wired or wireless network). The service provider 14 would print the order and mail the prints back to the user.

Instead of, or in addition to, composing a print order, the user may choose to transmit one or more images to others. These images can include the "creative" images and/or text described above. The user selects the images and the person(s) who will receive them, from the group of addresses loaded into the camera 12 via the process described earlier (the software application running on the home PC 10). The e-mail order information is provided in the utilization file that gives the e-mail address and includes pointers to the image files that store the images required to "fulfill" the e-mail order.

If the camera 12 includes a transmitter, e.g., a cellular connection in the communications interface 28, the camera 12 could include and initiate a "send" command that the user would enable after completing the e-mail order. This command would automatically send the appropriate images to the appropriate user's e-mail accounts through the network 31 using the appropriate communications protocol (i.e., FTP, mailto). Alternatively, the camera 12 can be placed in a docking unit (not shown) containing the modem. The images can then be automatically transmitted to the service provider 14, when the camera 12 is inserted into the dock. Alternatively, the memory card 36 could be removed from the camera 12 and placed in a kiosk, which would then transmit the images and bill the user's charge card.

Instead of, or in addition to, composing a print order and/or an e-mail order, the user may choose to transmit one or more images to their "electronic photo album" account, which could be maintained by the service provider 14 (or alternatively could be maintained on the user's home computer 10) in an image "album" storage 52. In this case, the user selects the images to be transferred to their photo album, and optionally selects what group of users might be allowed to view the images. The groups may include "Self only", "Self plus immediate family only", and "All" (i.e., family, friends). The information may include text, which may be input and selected as described in U.S. Pat. No. 5,633,678, "An Electronic Still Camera for Capturing and Categorizing Images", filed Dec. 20, 1995, and assigned to the assignee of the present application, the disclosure of which is herein incorporated by reference.

Instead of having the camera 12 communicate directly to the "downstream" service provider 14 over the communications network 31, the communications network 31 from the camera 12 could alternatively be connected to an internet service provider (ISP) (not shown) such as AOL (America On Line), Earthlink, and Eznet. The "downstream" service provider 14 would then be connected to all ISPs via the internet, eliminating the need to maintain a separate communications network. The ISP would transfer the utilization file data and images needed to order prints and album images to the downstream service provider. The ISP could itself handle e-mailing of images to other users, using the data and images in the utilization file.

The utilization order information is provided in the utilization file. The general file organization is shown in FIG. 4, and a detailed example of the file contents of an elaborate

utilization file is given in Appendix I. This file may be encrypted to prevent unauthorized use of the sensitive information, such as the user's credit card number. Referring to Appendix I, a Global information section (lines 2-26) provides the customer information (name, address, credit card), as well as the time the order was placed, and whether it has been processed or not.

The file may contain one or more Print Order sections. For example, lines 28-37 describe a print order of "standard" size (4"×6") prints of the images made on a silver halide based CRT printer. Line 34 indicates that two copies of the image referenced in line 33 will be printed, while only one copy of the images referenced in lines 35-36 is printed. A second print order section (lines 39-55) indicates a large size print (24"×36") should be made on a silver halide printer and mounted in particular in a walnut frame. This printer should be sent via UPS to the address shown in lines 47-52. The image is the composite shown in FIG. 3, which is described in the CreativeDetail section (lines 76-90).

An e-mail order section (lines 57-65) provides the e-mail address and a list of images that should be sent to this address. An album order section (lines 67-72) provides a means for adding images to the users on-line photo album. The user can classify the images under a particular heading (e.g., "vacation" images) and indicate who is allowed to access the images via the internet.

A Creative Detail section (lines 74-90) defines each creative image, such as the image in FIG. 3. It also describes user defined text (line 81). Multiple templates and user text options may be downloaded from the host computer to a memory card 36 that is then inserted into the camera 12, prior to taking pictures. The template (background) may be an identification code that is only added, for example, during printing. In this case, the template is not viewed when the image is displayed on the camera 12. Alternatively, a low resolution version of the templates desired by the user can be stored in the camera 12, so that the user can preview the final composite image. A high resolution version of the template can be used by the service provider to print the final composite image. The user may decide to crop and rotate the image (lines 86-87) prior to inserting it into the creative background.

Finally, an image detail section (92-102) describes the file type (e.g., FlashPix, JPEG, TIFF) and location of each image. In this example, the three images are all FlashPix images located on the memory card "Local Card" in the "vacation" folder.

Most of the information in GlobalInfo and CreativeDetail sections of the digital camera utilization file, for example the addresses and creative text, is downloaded from the host computer to the camera prior to picture taking. After reviewing the images, the user uses the image LCD and user interface to select which images to print, e-mail, and album. The print size, e-mail, albuming, and creative options are offered by pull-down menus that match the options provided by the service providers they have selected on the computer and downloaded to the camera 12 (via the memory card 36). The full utilization file (i.e., Print order, e-mail order) is then created by the camera based on the user selections.

A much simpler print utilization file is shown in Appendix II. In this case, the camera 12 simply allows a print order to be created. The memory card 36 containing the images and the simple utilization file is then inserted into the home PC 10, the home printer, or the walk-up kiosk 16 or sent to a service provider via a communications interface. The proper number of each selected image is then automatically printed, without further user intervention.

Instead of providing the utilization information for multiple images in a single utilization file, other embodiments are possible. For example, the camera may create three utilization files, one containing the information needed to produce a print order, a second containing information needed to provide electronic albuming, and a third containing e-mail order information. Alternatively, the utilization information may be provided with each image file, as shown in FIG. 5. In this embodiment, the print order information describing the number and size of each image to be printed is included in tags provided within each image file. For example, image file #1 contains the image data and a tag indicating that the user has requested one standard size print. Image file #2 does not contain a print tag (or alternatively could include a tag with the number of prints set equal to zero) so no prints will be made of image #2. Image file #3 includes a first print tag indicating that the user has requested two standard size prints, and a second tag indicating that the user has also requested a single 8"×10" size enlargement.

The invention has been described with reference to a preferred embodiment. However, it will be appreciated that variations and modifications can be effected by a person of ordinary skill in the art without departing from the scope of the invention.

What is claimed is:

1. An electronic camera for capturing images to be transferred to at least one e-mail address, the electronic camera comprising:

- (a) an image sensor for capturing a plurality of images;
- (b) a first memory for storing the plurality of images;
- (c) a second memory for storing a plurality of e-mail addresses;
- (d) a processor for producing a utilization file;
- (e) a display coupled to the first memory for displaying at least one of the plurality of stored images; and
- (f) a user interface for selecting at least one e-mail address stored in the second memory and for scrolling through the plurality of images stored in the first memory in order to display and select at least one image to be transferred to the selected at least one e-mail address, wherein the utilization file identifies the at least one selected e-mail address and the at least one image to be transferred to the at least one selected e-mail address.

2. The electronic camera as claimed in claim 1 wherein the first memory is a removable memory card.

3. The electronic camera as claimed in claim 1 further including a communications interface which interfaces to a communications network for transferring the at least one selected image to the at least one selected e-mail address.

4. The electronic camera as claimed in claim 3 wherein the communications interface includes a transmitter.

5. The electronic camera as claimed in claim 4 wherein the transmitter provides a cellular connection.

6. The electronic camera as claimed in claim 4 wherein the electronic camera provides a send command to initiate transfer of the at least one selected image to the at least one selected e-mail address using the transmitter.

7. The electronic camera as claimed in claim 1 further including a separate docking unit having a modem for transferring the at least one selected image to the at least one selected e-mail address.

8. The electronic camera as claimed in claim 7 wherein the at least one selected image is transmitted to a service provider, and the service provider then transfers the at least one selected image to the at least one selected e-mail address.

9. The electronic camera as claimed in claim 1 wherein the plurality of images are stored in a corresponding plurality of digital image files.

10. The electronic camera as claimed in claim 9 wherein the digital image files are JPEG files.

11. The electronic camera as claimed in claim 1 wherein the utilization file identifies at least two digital images.

12. The electronic camera as claimed in claim 1 wherein the utilization file identifies the camera owner.

13. A method for capturing images to be transferred to at least one e-mail address, comprising:

- (a) storing a plurality of e-mail addresses in a memory of an electronic camera;
- (b) capturing a plurality of images of scenes with the electronic camera;
- (c) storing the plurality of images in a memory of the electronic camera;
- (d) providing a user interface in the electronic camera for selecting at least one e-mail address from the stored plurality of e-mail addresses and for scrolling through the plurality of stored images in order to display and select particular images to be transferred from the electronic camera to the selected at least one e-mail address;
- (e) transferring the selected images to the selected at least one e-mail address.

14. The method as claimed in claim 13 wherein the plurality of e-mail addresses are transferred from a separate device to the electronic camera.

15. The method as claimed in claim 14 wherein the separate device is a PC.

16. The method as claimed in claim 13 further including interfacing to a communications network and transferring the selected images to the at least one selected e-mail address.

17. The method as claimed in claim 16 wherein the communications network includes a cellular transmitter.

18. The method as claimed in claim 13 wherein the selected images are transmitted to a service provider, and the service provider then transfers the selected images to the at least one selected e-mail address.

19. The method as claimed in claim 13 further including producing a utilization file that identifies the at least one selected e-mail address and the selected images.

20. The method as claimed in claim 13 wherein the plurality of images is stored in a corresponding plurality of JPEG image files.

DIGITAL CAMERA WITH COMMUNICATIONS INTERFACE FOR SELECTIVELY TRANSMITTING IMAGES OVER A CELLULAR PHONE NETWORK AND A WIRELESS LAN NETWORK TO A DESTINATION

CROSS-REFERENCE TO RELATED APPLICATIONS

This is a continuation of U.S. Ser. No. 11/692,224 filed Mar. 28, 2007, now U.S. Pat. No. 7,742,084, which is a continuation of U.S. Ser. No. 09/783,437 filed Feb. 14, 2001 (which issued as U.S. Pat. No. 7,256,823 on Aug. 14, 2007, which is now Reissue application Ser. No. 12/540,610) which is a divisional of U.S. Ser. No. 09/004,046 filed Jan. 7, 1998 (now U.S. Pat. No. 6,784,924 which issued on Aug. 31, 2004) which claims the benefit of U.S. Provisional Application No. 60/037,962 filed Feb. 20, 1997

FIELD OF THE INVENTION

The invention relates generally to the filed of photography, and in particular to electronic photography. More specifically, the invention relates to a digital camera that interfaces with a host computer.

BACKGROUND OF THE INVENTION

Digital cameras, such as the Kodak Digital Science DC25™ camera, allow images to be utilized on a home computer (PC) and to be incorporated into e-mail documents and personal home pages on the World Wide Web. Presently, images must be copied to the PC and transmitted as e-mail, for example using an online service or an Internet Service Provider (ISP), via a modem from the user's PC. It would be desirable to be able to transmit pictures directly from the digital camera instead of first transferring the pictures to a PC. For instance, on a vacation trip, it is desirable to immediately share pictures with friends or relatives via e-mail or Internet access. It is also desirable to transmit pictures from a location without PC access in order to free up camera storage to take additional pictures. There are a wide variety of connection means to online services such as America On Line, ISPs, and bulletin board services. Each of these services typically requires an account name and password, as well as local telephone access numbers, and specific communications settings. It would be difficult to provide an easy-to use means with buttons or menus on a small digital camera to input and/or modify all of these required settings.

SUMMARY OF THE INVENTION

The present invention is directed to overcoming one or more of the problems set forth above. Briefly summarized, according to one aspect of the present invention, the invention resides in a digital camera for capturing a plurality of images comprising an image sensor for receiving incident light of a scene, the digital camera capturing an image corresponding to the incident light of the scene; a display for displaying the plurality of captured images and for displaying a menu of destinations; at least one user input for selection of at least one image from the plurality of captured images and a destination from the menu of destinations displayed on the display; a communications interface for transmitting the at least one selected image to the selected destination over one of a plurality of networks, the plurality of networks including at least

2

two different types of wireless networks; a memory; and a processor coupled to the image sensor, the display, the at least one user input, the communications interface, and the memory, the processor controlling the transmission of the at least one selected image to the selected destination using either one of the at least two different types of wireless networks.

These and other aspects, objects, features and advantages of the present invention will be more clearly understood and appreciated from a review of the following detailed description of the preferred embodiment and appended claims, and by reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a system block diagram of the invention.

FIG. 2 is a diagram showing the steps used to automatically transmit images using the network configuration file.

FIG. 3 is a diagram of an image file.

FIG. 4 is a diagram showing several versions of the network configuration file.

DETAILED DESCRIPTION OF THE INVENTION

Because imaging systems and devices are well known, the present description will be directed in particular to elements forming part of, or cooperating more directly with, apparatus in accordance with the present invention. Elements not specifically shown or described herein may be selected from those known in the art. Some aspects of the present description may be implemented in software. Unless otherwise specified, all software implementation is conventional and within the ordinary skill in the programming arts.

A system block diagram of the invention is shown in FIG. 1 including an electronic still camera 10, a host computer (PC) 12 and a service provider 14. The camera includes an optical section 20 for imaging a scene upon a CCD sensor 22 and generating an image signal, a liquid crystal display (LCD) 24 for displaying images and other information, a number of user input buttons 26, both permanent memory 28 and removable memory 30, and an internal communications interface (32) (e.g., modem). This interface may connect to a variety of known networks, such as a public switched telephone network (PSTN), ISDN, an RF cellular phone network, or Ethernet. The camera 10 also includes a microprocessor 34 for generally controlling the camera functions, as well as the interchange of data with the host PC 12 and the memory card 30 through a host PC interface 36 and a memory card interface 38, respectively. Besides the host PC 12, the system includes a network connection 40 to the online service or ISP (Internet Service Provider) 14. Alternately, the network 40 can connect to the user's home PC 12.

When the camera 10 is first purchased (or at any time thereafter), it is connected to the PC 12 via the host PC 36 interface and a software application (stored on a disc 45) running on the host PC 12 will enable the user to specify the name of a destination ISP or online service and to input from the host PC keyboard 44 the appropriate communication settings and account information. This information generates a network configuration file, which then can then be downloaded to the camera 10 through the host PC interface 36, which may be a wired or infrared (e.g., IrDA) interface, and written to the camera's internal memory 28 and/or the removable memory card 30. Alternatively, a host PC equipped with a memory card reader/writer 42 can write the information directly to the card 30 without connecting the camera through its host PC interface 36. Also, this information could be

3

predetermined by the user and stored in a "preferences" file on the host PC 12 and then transferred to the camera 10 from this file without further intervention by the user. Multiple sets of destination services can be stored on the memory card 30. Typically, keyword or graphic descriptors (e.g., icons) accompany the information in the network configuration file about destination services to enable easy access by the camera user.

The steps used to automatically transmit images using the network configuration file are shown in FIG. 2. After disconnecting the camera from the host PC, the user operates the camera to take pictures (step 50). This is typically done at a remote location, for example while traveling to another city. As the user takes or reviews images on the image LCD display, the decision can be made to transmit one or more images (step 52). This is done by choosing one of the keywords or icons in a menu 54 shown in FIG. 2, which are displayed on the LCD 24 and selected, e.g., through the user buttons 26. (Note that a camera will typically only include a subset (only those desired by the user) of all the different services shown.) The selected image files may be tagged with a code (step 56) indicating which service is requested, as shown in FIG. 3. (Alternately, an "image utilization" file can be created in the camera storing a list of images to be transmitted by a particular method, as described in the cross-referenced copending patent application (U.S. Ser. No. 60/037,963). As described in that patent application, the details of an order, e.g., number of print copies to be made from an image and the size of the prints and/or a list of images to be e-mailed to various recipients, is written into the "utilization" file, which identifies the order and includes pointers to the image files that store the images required to "fulfill" the order. The "utilization" file is stored in the internal memory 28 or the memory card 30.)

Next, the system determines whether a request exists to send an image (step 58). If no request is present, the image and associated data is stored in either permanent memory 28 or the memory card 30 (step 59). (Typically, all images are initially saved in memory whether eventually sent or not.) Otherwise, if there is a request to send an image, the user ensures that the camera is connected to the appropriate service (wired telephone line, cellular phone, kiosk, etc.) and pushes a "send" button in the user button section 26, or selects a "send" menu option on the LCD 24. The camera then utilizes the appropriate network configuration file, shown in FIG. 4. Each network configuration file contains items such as the protocol type, phone number, etc., as described in Appendix I. The user password may be checked against the password in the network configuration file to ensure that the user is authorized to connect the camera to the desired service (step 60). Alternately, the stored password in the appropriate configuration file can be used. Next, the camera uses the parameters in the configuration file to establish communications with the service and send one or more image files as selected by the user (steps 62). The service receiver interprets the system commands issued by the camera from the network configuration file list and sends appropriate feedback (such as "transfer in progress" and "transfer complete") which are interpreted by the camera and displayed on the LCD 24 (steps 64).

For example, when the camera uses a normal wired telephone (Public Switched Telephone Network) connection (i.e., network 40) to the camera's internal modem 32, after the user selects the images to be sent and presses the "send" button, the camera performs the following steps without user intervention:

1) Read the appropriate connection parameters from the network configuration file (on the memory card 30 or internal

4

camera memory 28), dial the phone and establish the connection to the destination service 14.

2) Read the user's account name and password and transmit these to "log-on" to the service 14.

3) Using the appropriate communications protocol (FTP, mailto, etc.), transmit the selected image or images to the destination service 14.

The invention has been described with reference to a preferred embodiment. However, it will be appreciated that variation and modifications can be effected by a person of ordinary skill in the art without departing from the scope of the invention.

APPENDIX I

These are descriptions of the tags listed in the previous drawing:

Protocol Type

Each communication method has its own protocol, or rules to communicate. This tag identifies that protocol and where to find it. For example, the Network may use TCP/IP and a modem may use XModem.

Phone Number

This is the number of the receiving service. If internet access is requested, this could be the number of the Internet Service Provider. For ISDN, some systems require two phone numbers, dialed and connected to in sequence.

Default Settings

Standard settings that make the communications device compatible with the imaging device.

Modem Control String

Modem and communications devices have a command language that can set them up before they are used. For example, modems have many options controlled by command strings including volume level, the amount of time the carrier is allowed to fail before the system hangs up, and so on.

Account Data

This can be internet account data, charge number data, phone card data, billing address, and data related to the commerce part of the transmission.

Password

Any password needed to get into the communications system. Other passwords to get into the remote application or destination are located in the System Commands section.

System Commands

These are commands that control the end destination.

Error Protocol

In cellular and some other wireless communications, error protocols are used to increase the robustness of the link. For example, MNP10 or ETC may be used for cellular links.

Radio Type

The type of radio used for this communications feature may be identified here. Some cell phones have modems built in, others will have protocols for many communications functions built in. The radio type will make the imaging device adapt to the correct interface.

IOC

ISDN Ordering Code identifies what features are available on the ISDN line provided by the teleco. It is used to establish the feature set for that communications link.

Internet Service Provider

This identifies the actual service provider and any specific information or sequence of information that the service wants to see during connection and logoff. It also tells the device how to handle the return messages, like "time used" that are returned by the server.

5

Commands to Receiver

This may be a list of commands to control the receiving application. For example, a command to print one of the images and save the data to a particular file on a PC may be embedded here.

Return Status Requests

This tag can set up the ability of the application to tell if an error has occurred, or what the status of the application might be. The data here will help the device decide if it should continue communicating and a set user interface response can be developed around this feedback.

The invention claimed is:

1. A digital camera for capturing a plurality of images comprising:

an image sensor for receiving incident light of a scene, the digital camera capturing an image corresponding to the incident light of the scene;

a display for displaying the plurality of captured images and for displaying a menu of destinations;

at least one user input for selection of at least one image from the plurality of captured images and a destination from the menu of destinations displayed on the display;

a communications interface for transmitting the at least one selected image to the selected destination over one of a plurality of networks, the plurality of networks including at least two different types of wireless networks;

a memory; and

a processor coupled to the image sensor, the display, the at least one user input, the communications interface, and the memory, the processor controlling the transmission of the at least one selected image to the selected destination using either one of the at least two different types of wireless networks.

2. The digital camera of claim 1, wherein the at least two different types of wireless networks include a cellular phone network and a wireless LAN.

3. The digital camera of claim 2, wherein the image sensor, the display, the at least one user input, and the communications interface are directly coupled to the processor, and the memory is coupled to the processor via a memory interface, and wherein the memory stores first information used by the processor to control the communications interface to enable transmission over the cellular phone network, and stores second information used by the processor to control the communications interface to enable transmission over the wireless LAN.

4. The digital camera of claim 3, wherein the first information is stored in a first configuration file and the second information is stored in a second configuration file.

5. The digital camera of claim 4, wherein the first and second configuration files are generated by a separate device, and transferred from the separate device to the memory of the digital camera.

6. The digital camera of claim 5, wherein the separate device is a computer.

6

7. The digital camera of claim 1, wherein the memory is an internal memory.

8. The digital camera of claim 1, wherein the memory is a removable memory card.

9. The digital camera of claim 3, wherein the first information includes a phone number associated with the selected destination.

10. The digital camera of claim 3, wherein the first and second information include account data.

11. A digital camera for capturing a plurality of images comprising:

an image sensor for receiving incident light of a scene, the digital camera capturing an image corresponding to the incident light of the scene;

a display for displaying the plurality of captured images; at least one user input for selection of at least one image from the plurality of captured images;

a communications interface for transmitting the at least one selected image over one of a plurality of networks, the plurality of networks including a cellular phone network and a wireless LAN;

a processor coupled to the image sensor, the display, the at least one user input, and the communications interface, the processor controlling the transmission of the at least one selected image to a destination;

a memory coupled to the processor for storing first information used by the processor to control the communications interface to transmit to the destination over the cellular phone network when the camera is connected to the cellular phone network, and for storing second information used by the processor to control the communications interface to transmit to the destination over the wireless LAN when the camera is connected to the wireless LAN.

12. The digital camera of claim 11, wherein the first information is stored in a first configuration file and the second information is stored in a second configuration file.

13. The digital camera of claim 12, wherein the first and second configuration files are generated by a separate device, and transferred from the separate device to said memory of said digital camera.

14. The digital camera of claim 13, wherein the separate device is a computer.

15. The digital camera of claim 11, wherein the memory is an internal memory.

16. The digital camera of claim 11, wherein the memory is a removable memory card coupled to the processor via a memory card interface, and wherein the image sensor, the display, the at least one user input, and the communications interface are directly coupled to the processor.

17. The digital camera of claim 11, wherein the first information includes a phone number associated with the destination.

18. The digital camera of claim 11, wherein the first and second information include account data.
