**HANDHELD COMPUTER SYSTEM THAT
ATTEMPTS TO ESTABLISH AN
ALTERNATIVE NETWORK LINK UPON
FAILING TO ESTABLISH A REQUESTED
NETWORK LINK**

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention generally relates to the field of computer systems. More particularly, the present invention relates to the field of network functionality that attempts to establish a requested network link or, if necessary, attempts to establish any other alternative network link that a user has previously designated for the requested network link.

2. Related Art

Computers and other electronic systems or devices (e.g., personal digital assistants) have become integral tools used in a wide variety of different applications, such as in finance and commercial transactions, computer-aided design and manufacturing, health care, telecommunication, education, etc. Computers along with other electronic devices are finding new applications as a result of advances in hardware technology and rapid development in software technology. Furthermore, the functionality of a computer system or other type of electronic system or device is dramatically enhanced by coupling these stand-alone devices together in order to form a networking environment. Within a networking environment, users may readily exchange files, share information stored on a common database, pool resources, and communicate via electronic mail (e-mail) and via video teleconferencing. Furthermore, computers or other types of electronic devices which are coupled to the Internet provide their users access to data and information from all over the world.

The functionality of an electronic system (e.g., a palmtop computer system, a desktop computer system, a cellular phone, a pager, etc.) is enhanced by including an electronic display device. On occasion, the electronic system includes one or more communication ports for exchanging or sharing data with other electronic systems or with a network. For example, an infrared (IR) communication port, a RF (radio frequency) communication port, or other type of communication port can be incorporated into the electronic system. A communication port is positioned in the electronic system according to a variety of factors, such as space requirements, industry standards, and convenience to a user.

A personal digital assistant (commonly referred to as a PDA) is a palmtop computer system. It is appreciated that the personal digital assistant is a portable handheld device that is used as an electronic organizer which has the capability to store a wide range of information that includes daily appointments, numerous telephone numbers of business and personal acquaintances, and various other information. Moreover, the personal digital assistant can also access information from the Internet, as mentioned above. In particular, the personal digital assistant can browse Web pages located on the Internet. Typically, the personal digital assistant includes an electronic display device having a display area (e.g., a screen) that is smaller in size relative to a display area associated with a standard-sized electronic display device (e.g., 15 inch monitor, 17 inch monitor, etc.) which is part of a desktop computer system or a laptop computer system.

Typically, the personal digital assistant includes one or more communication ports (e.g., an IR communication port, a RF (radio frequency) communication port, a serial communication port, an Ethernet communication port, a cellular phone communication port, etc.). For example, a IR commu-

2

nication port is positioned along the top edge of the personal digital assistant so that a user can conveniently view and read the electronic display device and at the same time communicate with another electronic system located across from the user while the user holds the personal digital assistant.

Moreover, the network capability of the personal digital assistant enhances a user's experience. As new network technologies emerge, additional network functionality is incorporated into the personal digital assistant. For example, a variety of wireless networks are being deployed to serve a wide range of devices including a personal digital assistant. Having access to many different types of networks improves the productivity of the user and increases demand for the personal digital assistant. However, the personal digital assistant may not always be able to establish a network link with some of these emerging networks because of numerous reasons. Some of these reasons include: insufficient network capacity, technical network difficulties, and slow rollout of the coverage area of the emerging networks.

Typically, if the personal digital assistant fails to establish a requested network link, the user has to reconfigure the network functionality of the personal digital assistant so that, on a subsequent attempt to establish a network link, another type of network link is attempted. If the personal digital assistant fails again to establish the requested network link, the user again has to reconfigure the network functionality of the personal digital assistant so that, on another attempt to establish a network link, yet another type of network link is attempted. Such intervention by the user degrades the user experience and increases user frustration. Moreover, the situation can only get worse in the future with the continual development of more network technologies.

SUMMARY OF THE INVENTION

A computer system that attempts to establish an alternative network link upon failing to establish a requested network link is described. The computer system may encounter conditions where access to numerous networks, in particular wireless networks, is not available. Rather than only providing an error message to the user upon a failed attempt to establish the requested network link, the computer system determines whether the user has designated an alternative network link in case the requested network link cannot be established, whereas the alternative network link is selected from the plurality of network links that the computer system is configured to support. If an alternative network link has been designated, the computer system attempts to establish the alternative network link. Hence, the user experience is made smooth and uneventful when the requested network link cannot be established.

In a chain implementation, the user designates one or several alternative network links for a particular network link. Upon failure to establish the particular network link, the computer system sequentially attempts to establish one of the alternative network links. The user has wide flexibility. For example, the user can omit providing an alternative network link for some of the network links supported by the computer system. Moreover, the user can designate any number of alternative network links for any of the network links supported by the computer system.

In a loop implementation, the user designates one or several alternative network links for a particular network link. The computer system attempts the particular network link and then, if the particular network link cannot be established, attempts to establish the alternative network link(s). If no network link was established, the computer system again

attempts to establish the particular network link and, if necessary, again attempts to establish the alternative network link(s). The computer system can continue this loop until a network link is established or until the user decides to stop the loop.

These and other advantages of the present invention will no doubt become apparent to those of ordinary skill in the art after having read the following detailed description of the preferred embodiments which are illustrated in the drawing figures.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and form a part of this specification, illustrate embodiments of the invention and, together with the description, serve to explain the principles of the present invention.

FIG. 1 illustrates a block diagram of a first exemplary network environment including a personal digital assistant on which the present invention can be practiced.

FIG. 2A illustrates a block diagram of a second exemplary network environment including a personal digital assistant on which the present invention can be practiced, whereas the personal digital assistant is coupled to other computer systems and the Internet via a cradle device.

FIG. 2B illustrates a block diagram of a third exemplary network environment including a personal digital assistant on which the present invention can be practiced, whereas the personal digital assistant is coupled to other computer systems and the Internet via a network port.

FIG. 3 illustrates a top side perspective view of a personal digital assistant on which the present invention can be practiced.

FIG. 4 illustrates a bottom side perspective view of the personal digital assistant of FIG. 3.

FIG. 5 illustrates a perspective view of another personal digital assistant on which the present invention can be practiced.

FIG. 6 illustrates a logical circuit block diagram of a personal digital assistant on which the present invention can be practiced.

FIG. 7 illustrates a perspective view of a cradle device for connecting the personal digital assistant to other systems via a communication interface.

FIG. 8 illustrates a software environment on which the present invention can be practiced.

FIG. 9 illustrates a plurality of network links each having an alternative network link designation in accordance with an embodiment of the present invention.

FIG. 10 illustrates a first plurality of network links each having an alternative network link designation and a second plurality of network links each having an alternative network link designation in accordance with an embodiment of the present invention.

FIG. 11 illustrates operation of a first loop implementation for attempting multiple network links in accordance with an embodiment of the present invention.

FIG. 12 illustrates operation of a second loop implementation for attempting multiple network links in accordance with an embodiment of the present invention.

FIG. 13 illustrates a message displayed to a user in accordance with an embodiment of the present invention.

FIG. 14 illustrates a flow chart showing a method of enabling a user to provide the alternative network link designations for the network links supported by a personal digital assistant in accordance with an embodiment of the present invention.

FIG. 15 illustrates a flow chart showing a method of establishing a network link on a personal digital assistant in accordance with an embodiment of the present invention.

The drawings referred to in this description should not be understood as being drawn to scale except if specifically noted.

DETAILED DESCRIPTION OF THE INVENTION

Reference will now be made in detail to the preferred embodiments of the present invention, examples of which are illustrated in the accompanying drawings. While the invention will be described in conjunction with the preferred embodiments, it will be understood that they are not intended to limit the invention to these embodiments. On the contrary, the invention is intended to cover alternatives, modifications and equivalents, which may be included within the spirit and scope of the invention as defined by the appended claims. Furthermore, in the following detailed description of the present invention, numerous specific details are set forth in order to provide a thorough understanding of the present invention. However, it will be recognized by one of ordinary skill in the art that the present invention may be practiced without these specific details. In other instances, well known methods, procedures, components, and circuits have not been described in detail as not to unnecessarily obscure aspects of the present invention.

Although the description of the present invention will focus on a personal digital assistant or handheld computer system, the present invention can be practiced on other types of computer systems.

Computer System Environment

One of the common types of computer systems which can be used to practice the present invention is referred to as a personal digital assistant, or commonly called a PDA. The personal digital assistant is a pocket sized electronic organizer with the capability to store telephone numbers, addresses, daily appointments, and software that keeps track of business or personal data such as expenses, etc. Furthermore, the personal digital assistant also has the ability to connect to a personal computer, enabling the two devices to exchange updated information. Additionally, the personal digital assistant can also be connected to a modem, enabling it to have electronic mail (e-mail) capabilities over the Internet along with other Internet capabilities. Alternatively, the personal digital assistant can have a network port (e.g., an Ethernet Local Area Network (LAN) port) to access a network coupled to the Internet, enabling the personal digital assistant to have electronic mail (e-mail) capabilities over the Internet along with other Internet capabilities. Moreover, an advanced personal digital assistant can have Internet capabilities over a wireless communication interface (e.g., radio interface). In particular, the personal digital assistant can be used to browse Web pages located on the Internet. The personal digital assistant can be coupled to a networking environment. It should be appreciated that embodiments of the present invention are well suited to operate within a wide variety of computer systems, some of which can be communicatively coupled to a networking environment.

FIG. 1 is a block diagram of a first exemplary network environment 50 including a personal digital assistant 100 on which the present invention can be practiced. The personal digital assistant 100 is also known as a palmtop or palm-sized electronic system or computer system. Here, the personal digital assistant 100 has the ability to transmit and receive

5

data and information over a wireless communication interface (e.g., a radio interface). The personal digital assistant **100** is one exemplary computer system on which the present invention can operate. The present invention can operate on any other type of computer system.

In one embodiment, base station **32** is both a transmitter and receiver base station which can be implemented by coupling it into an existing public telephone network **34**. Implemented in this manner, base station **32** enables the personal digital assistant **100** to communicate with a proxy server computer system **36**, which is coupled by wire **35** to the existing public telephone network **34**. Alternatively, a private telephony system, a private data network, or any other communication network can be implemented as alternatives for the existing public telephone network **34**. Furthermore, proxy server computer system **36** is coupled to the Internet **52**, thereby enabling the personal digital assistant **100** to communicate with the Internet **52**. Alternatively, a router, a switch, or any other interface device can be implemented as alternatives for the proxy server computer system **36**. It should be appreciated that within the present embodiment, one of the functions of proxy server **36** is to perform operations over the Internet **52** on behalf of the personal digital assistant **100**. For example, proxy server **36** has a particular Internet address and acts as a proxy device for the personal digital assistant **100** over the Internet **52**. It should be further appreciated that other communications networks may be utilized in practicing the present invention.

The data and information which are communicated between base station **32** and the personal digital assistant **100** are a type of information and data that can conventionally be transferred and received over a public telephone wire network system. However, a wireless communication interface is utilized to communicate data and information between the personal digital assistant **100** and base station **32**. It should be appreciated that one embodiment of a wireless communication system in accordance with the present invention is the Mobitex wireless communication system.

FIG. 2A illustrates a block diagram of a second exemplary network environment **51A** including a personal digital assistant **100** on which the present invention can be practiced, whereas the personal digital assistant **100** is coupled to other computer systems and the Internet via a cradle device. Network system **51A** comprises a host computer system **56** which can either be a desktop computer system as shown, or, alternatively, can be a laptop computer system **58**. Optionally, more than one host computer system **56** can be used within network system **51A**. Host computer systems **58** and **56** are shown connected to a communication bus **54**, which in one embodiment can be a serial communication bus, but could be of any of a number of well known designs (e.g., a parallel bus, Ethernet Local Area Network (LAN), etc.). Optionally, bus **54** can provide communication with the Internet **52** using a number of well known protocols.

Importantly, bus **54** is also coupled to a cradle **60** for receiving and initiating communication with the personal digital assistant **100**. Cradle **60** provides an electrical and mechanical communication interface between bus **54** (and any device coupled to bus **54**) and the personal digital assistant **100** for two-way communications. The personal digital assistant **100** also contains a wireless infrared communication mechanism **64** for sending and receiving information from other devices.

FIG. 2B illustrates a block diagram of a third exemplary network environment **51B** including a personal digital assistant **100** on which the present invention can be practiced, whereas the personal digital assistant **100** is coupled to other

6

computer systems **58** and **56** and the Internet **52** via a network port **55**. As depicted in FIG. 2B, the personal digital assistant **100** includes a network port **55** to couple to a communication bus **54**, whereas the desktop computer system **56** and the laptop computer system, as well as the Internet **52**, can be coupled to the communication bus **54**. The communication bus **54** can be implemented in any format, such as an Ethernet Local Area Network (LAN).

With reference to FIGS. 1, 2A, and 2B, it is appreciated that the personal digital assistant **100** can be used in a network environment combining elements of networks **50**, **51A**, and **51B**. That is, the personal digital assistant **100** can include a wireless infrared communication mechanism, a signal (e.g., radio) receiver/transmitter device, and a network port.

FIG. 3 is a perspective illustration of the top face **100a** of one embodiment of the personal digital assistant or palmtop computer system **100**. The top face **100a** has a display screen **105** surrounded by a bezel or cover. A removable stylus **80** is also shown. The display screen **105** is a touch screen able to register contact between the screen and the tip of the stylus **80**. The stylus **80** can be of any material to make contact with the display screen **105**. The top face **100a** also has one or more dedicated and/or programmable buttons **75** for selecting information and causing the computer system to implement functions. The on/off button **95** is also shown. Moreover, a user is able to control specific functionality of the personal digital assistant **100** by using its plurality of buttons **75** (e.g., to invoke telephone/address data, calendar data, to-do-list data, memo pad data, etc.). Furthermore, the user can utilize the stylus **80** in conjunction with the display screen **105** in order to cause the personal digital assistant **100** to perform a multitude of different functions. One such function is the selecting of different functional operations of the personal digital assistant **100**, which are accomplished by touching stylus **80** to specific areas of display screen **105**. Another such function is the entering of data into the exemplary personal digital assistant **100**.

FIG. 3 also illustrates a handwriting recognition pad **106** or "digitizer" containing two regions **106a** and **106b**. Region **106a** is for the drawing of alphabetic characters therein for automatic recognition, and region **106b** is for the drawing of numeric characters therein for automatic recognition. The stylus **80** is used for stroking a character within one of the regions **106a** and **106b**. The stroke information is then fed to an internal processor for automatic character recognition. Once characters are recognized, they are typically displayed on the screen **105** for verification and/or modification.

FIG. 4 illustrates the bottom side **100b** of one embodiment of the personal digital assistant or palmtop computer system **100** that can be used in accordance with various embodiments of the present invention. An extendible antenna **85** is shown, and also a battery storage compartment door **90** is shown. The antenna **85** enables the personal digital assistant **100** to be communicatively coupled to a network environment (as shown in FIG. 1) thereby enabling a user to communicate information with other electronic systems and electronic devices coupled to the network. A communication interface **180** is also shown. In one embodiment of the present invention, the communication interface **180** is a serial communication port, but could also alternatively be of any of a number of well-known communication standards and protocols (e.g., parallel, SCSI (small computer system interface), Firewire (IEEE 1394), Ethernet, etc.).

FIG. 5 illustrates a perspective view of another personal digital assistant **100** on which the present invention can be practiced. Here, the personal digital assistant **100** includes a display screen **105** and a handwriting recognition pad **106** or

“digitizer, as well one or more dedicated and/or programmable buttons 75 for selecting information and causing the personal digital assistant 100 to implement particular functions. It should be understood that the present invention can be practiced on personal digital assistants having other configurations and designs.

Referring now to FIG. 6, portions of the personal digital assistant 100 are comprised of computer-readable and computer-executable instructions which reside, for example, in computer-readable media of the personal digital assistant 100.

FIG. 6 is a block diagram of interior components of a personal digital assistant 100 on which the present invention can be practiced. The personal digital assistant 100 includes an address/data bus 110 for communicating information, a central processor 101 coupled to the bus 110 for processing information and instructions, a volatile memory 102 (e.g., random access memory, static RAM, dynamic RAM, etc.) coupled to the bus 110 for storing information and instructions for the central processor 101 and a non-volatile memory 103 (e.g., read only memory, programmable ROM, flash memory, EPROM, EEPROM, etc.) coupled to the bus 110 for storing static information and instructions for the processor 101. The personal digital assistant 100 also includes an optional data storage device 104 (e.g., memory card, hard drive, etc.) coupled with the bus 110 for storing information and instructions. Data storage device 104 can be removable. As described above, the personal digital assistant 100 also includes an electronic display device 105 coupled to the bus 110 for displaying information to the computer user. In one embodiment, PC board 225 can include the processor 101, the bus 110, the ROM 103 and the RAM 102.

With reference still to FIG. 6, the personal digital assistant 100 also includes a signal transmitter/receiver device 108 which is coupled to bus 110 for providing a communication link between the personal digital assistant 100 and a network environment (e.g., network environments 50 and 51 of FIGS. 1 and 2, respectively). As such, signal transmitter/receiver device 108 enables central processor unit 101 to communicate wirelessly with other electronic systems coupled to the network. It should be appreciated that within the present embodiment, signal transmitter/receiver device 108 is coupled to antenna 85 (FIG. 5) and provides the functionality to transmit and receive information over a wireless communication interface. It should be further appreciated that the present embodiment of signal transmitter/receiver device 108 is well-suited to be implemented in a wide variety of ways. For example, signal transmitter/receiver device 108 could be implemented as a modem.

In one embodiment, the personal digital assistant 100 includes a communication circuit 109 coupled to bus 110. Communication circuit 109 includes an optional digital signal processor (DSP) 120 for processing data to be transmitted or data that are received via signal transmitter/receiver device 108. Alternatively, some or all of the functions performed by DSP 120 can be performed by processor 101.

Also included in the personal digital assistant 100 of FIG. 6 is an optional alphanumeric input device 106 which in one implementation is a handwriting recognition pad 106 (“digitizer”) having regions 106a and 106b (FIG. 3), for instance. Alphanumeric input device 106 can communicate information and command selections to processor 101. The personal digital assistant 100 also includes an optional cursor control or directing device (on-screen cursor control 107) coupled to bus 110 for communicating user input information and command selections to processor 101. In one implementation, on-screen cursor control device 107 is a touch screen device

incorporated with display device 105. On-screen cursor control device 107 is capable of registering a position on display device 105 where the stylus makes contact. The display device 105 utilized with the personal digital assistant 100 may be a liquid crystal display device, a cathode ray tube (CRT), a field emission display device (also called a flat panel CRT) or other display device suitable for generating graphic images and alphanumeric characters recognizable to the user. In the preferred embodiment, display device 105 is a flat panel display.

FIG. 7 is a perspective illustration of one embodiment of the cradle 60 for receiving the personal digital assistant or palmtop computer system 100. Cradle 60 includes a mechanical and electrical interface 260 for interfacing with communication interface 108 (FIG. 4) of the personal digital assistant 100 when the personal digital assistant 100 is slid into the cradle 60 in an upright position. Once inserted, button 270 can be pressed to initiate two-way communication between the personal digital assistant 100 and other computer systems or electronic devices coupled to serial communication 265.

Attempting an Alternative Network Link Upon Failure to Establish a Requested Network Link

Although the description of the present invention will focus on a personal digital assistant or handheld computer system, the present invention can be practiced on other types of computer systems.

In an embodiment, the personal digital assistant 100 attempts to establish an alternative network link upon failing to establish a requested network link. The personal digital assistant 100 may encounter conditions where access to numerous networks, in particular wireless networks, is not available. Rather than only providing an error message to the user upon a failed attempt to establish the requested network link, the personal digital assistant 100 determines whether the user has designated an alternative network link in case the requested network link cannot be established, whereas the alternative network link is selected from the plurality of network links that the personal digital assistant 100 is configured to support. If an alternative network link has been designated, the personal digital assistant 100 attempts to establish the alternative network link. Therefore, the user experience is made smooth and uneventful when the requested network link cannot be established. The present invention provides a simple manner to improve the user experience and reduce interruptions which annoy and frustrate the user.

In an embodiment, the personal digital assistant 100 can be configured to support a plurality of network links for communicating with numerous networks. These network links utilize a variety of network protocols and require a variety of physical connections (i.e., wired and wireless) to establish communication with the numerous networks. Examples of network protocols include: PPP (Point-to-Point Protocol), Ethernet, GPRS (General Packet Radio Service), TCP/IP (Transmission Control Protocol/Internet Protocol), Bluetooth wireless communication protocol, and IPX/SPX (Inter-network Packet Exchange/Sequenced Packet Exchange). Examples of physical connections include: wireless phone communication [e.g., GSM (Global System for Mobile Communications), CDMA (Code Division Multiple Access), TDMA (Time Division Multiple Access)], wired phone communication, serial line communication, network cable communication, parallel line communication, and wireless communication.

As discussed above, numerous wireless networks are being deployed throughout the country. The personal digital assis-

tant **100** can be configured to support several of these wireless networks. However, the numerous wireless networks may not be available in all regions of the country. The present invention enables the personal digital assistant **100** to easily initiate an alternative network link (e.g., to a wireless network or a wired network) when the requested network link (e.g., to a wireless network) cannot be established because any of a variety of reasons, such as insufficient network capacity, technical network difficulties, and spotty network coverage.

FIG. **8** illustrates a software environment on which the present invention can be practiced. In an embodiment, the software environment of the personal digital assistant **100** includes an application layer **10**, a shared library layer **20**, and an operating system layer **30**. This software environment provides the network functionality of the personal digital assistant **100**. Generally, an application **10** requests establishment of a network link (e.g., network link **A 40**, network link **B 50**, network link **C 60**, or network link **D 70**) in response to an action by the user or any other action. In particular, the application **10** sends a network open request (or makes a call) to a particular shared library **20** (e.g., a network library **20**), whereas the shared library **20** is a code resource database which makes available a variety of API services that applications **10** can request. Specifically, the network library **20** makes available functions which perform network-related tasks, such as opening a network link, sending data via the network link, reading data from the network link, etc.

In an embodiment, the network library **20** interfaces with the operating system **30** to establish (or open) the requested network link (e.g., network link **A 40**, network link **B 50**, network link **C 60**, or network link **D 70**). If the network library **20** (which has network open code) fails to establish the requested network link due to any of a variety of reasons (e.g., a network-related error, a time out error, a non-fatal operating system error), the network library **20** subsequently attempts to establish an alternative network link which has been previously designated by the user for the requested network link. It is possible for the user to omit designating the alternative network link. Moreover, the user can designate multiple alternative network links in case the first alternative network link cannot be established. Thus, the present invention gives the user a simple way to configure the personal digital assistant **100** to try an alternative network link when his/her first choice of network link is not available. It should be understood that the present invention can be practiced in other types of software environments.

FIG. **9** illustrates a plurality of network links supported by a personal digital assistant **100**, each having an alternative network link designation in accordance with an embodiment of the present invention. Here, the personal digital assistant **100** supports network link **A 40** (e.g., a wireless TCP/IP link), network link **B 50** (e.g., a wired TCP/IP link), network link **C 60** (e.g., a Bluetooth wireless link), and network link **D 70** (e.g., wireless IPX/SPX link).

Moreover, FIG. **9** illustrates a chain implementation. In the chain implementation, the user designates one or several alternative network links for a network link. In particular, the user selected network link **B**, network link **D**, and network link **C** as the alternative network link designation **40A** for network link **A 40**. The user selected network link **C** as the alternative network link designation **50A** for network link **B 50**. Moreover, the user selected network link **A**, network link **B**, and network link **D** as the alternative network link designation **60A** for network link **C 60**. In addition, the user selected network link **C** and network link **A** as the alternative network link designation **70A** for network link **D 70**. Upon

failure to establish the network link, the personal digital assistant **100** sequentially attempts to establish one of the alternative network links.

For example, in the case where the requested network link is the network link **A**, if the personal digital assistant **100** fails to establish the network link **A 40**, the personal digital assistant **100** attempts to establish the network link **B 50** based on the order specified in the alternative network link designation **40A**. Then, if the personal digital assistant **100** fails to establish the network link **B 50**, the personal digital assistant **100** attempts to establish the network link **D 70** based on the order specified in the alternative network link designation **40A**. Moreover, if the personal digital assistant **100** fails to establish the network link **D 70**, the personal digital assistant **100** attempts to establish the network link **C 60** based on the order specified in the alternative network link designation **40A**. Thus, the user is able to chain together a list of alternative network links for the personal digital assistant **100** to attempt in case the requested network link cannot be established. It is possible to proceed in a loop by attempting again to establish the network link **A 40** if the network link **C 60** cannot be established. The personal digital assistant **100** proceeds in a similar manner in the case where the requested network link is the network link **B 50**, the network link **C 60**, or the network link **D 70**.

The user has wide flexibility in creating the alternative network link designations **40A**, **50A**, **60A**, and **70A**, as is evident in FIG. **9**. For example, the user can omit providing an alternative network link for some of the network links supported by the personal digital assistant **100**. Moreover, the user can designate any number of alternative network links for any of the network links supported by the personal digital assistant **100**. The alternative network link designations **40A**, **50A**, **60A**, and **70A** reflect choices made by the user based on the user's priorities and the network links supported by the personal digital assistant **100**. It should be understood the present invention can be practiced with other number of network links.

FIG. **10** illustrates a first plurality of network links **140**, **150**, **160**, and **170** supported by a personal digital assistant **100**, each having an alternative network link designation, and a second plurality of network links **240**, **250**, **260**, and **270** supported by a personal digital assistant **100**, each having an alternative network link designation, in accordance with an embodiment of the present invention.

Moreover, FIG. **10** illustrates a first loop implementation in the case of the first plurality of network links **140**, **150**, **160**, and **170** supported by a personal digital assistant **100**. In the first loop implementation, the user designates an alternative network link for a network link. The personal digital assistant **100** attempts to establish the network link (e.g., network link **A 140**, network link **B 150**, network link **C 160**, or network link **D 170**) and then, if the network link cannot be established, attempts to establish the respective alternative network link (e.g., alternative network link designation **140A**, **150A**, **160A**, or **170A**). If no network link was established, the personal digital assistant **100** again attempts to establish the network link and, if necessary, again attempts to establish the respective alternative network link. The personal digital assistant **100** can continue this loop until any network link is established, until the user decides to stop the loop, until a predefined number of loop cycles have been performed, or until any other event occurs. Operation of the first loop implementation is depicted in FIG. **11**.

In addition, FIG. **10** illustrates a second loop implementation in the case of the second plurality of network links **240**, **250**, **260**, and **270** supported by a personal digital assistant

11

100. In the second loop implementation, the user creates a loop having several alternative network links. The personal digital assistant 100 attempts the network link (e.g., network link A 240, network link B 250, network link C 260, or network link D 270) and then, if the network link cannot be established, attempts to establish a respective alternative network link (e.g., alternative network link designation 240A, 250A, 260A, or 270A). If the respective alternative network link cannot be established, the personal digital assistant 100 proceeds to establish the particular alternative network link which is designated for the respective alternative network link. The personal digital assistant 100 proceeds in a similar manner if the particular alternative network link cannot be established. Moreover, the personal digital assistant 100 can continue this loop until any network link is established, until the user decides to stop the loop, until a predefined number of loop cycles have been performed, or until any other event occurs. Operation of the second loop implementation is depicted in FIG. 12.

FIG. 11 illustrates operation of a first loop implementation for attempting multiple network links in accordance with an embodiment of the present invention. For example, (as illustrated in table 200) in the case where the requested network link is the network link A 140, if the personal digital assistant 100 fails to establish the network link A 140, the personal digital assistant 100 attempts to establish the network link B 150 based on the alternative network link designation 140A.

In an embodiment, the personal digital assistant 100 provides a message to the user before proceeding to attempt the network link B 150. FIG. 13 illustrates a message 900 displayed to a user in accordance with an embodiment of the present invention. The message 900 informs the user that the requested network link could not be established. In addition, the message 900 enables the user to control whether the personal digital assistant 100 proceeds to the alternative network link. By selecting the option 910, the user enables the personal digital assistant 100 to attempt to establish the alternative network link. By selecting the option 920, the user stops the loop and prevents the personal digital assistant 100 from attempting to establish the alternative network link.

Continuing, (as illustrated in table 300 and by arrow 10) if the personal digital assistant 100 fails to establish the network link B 150, the personal digital assistant 100 attempts again to establish the network link A 140 based on the alternative network link designation 150A, since the network link A 140 is the respective alternative network link for the network link B 150. The personal digital assistant 100 can display the message 900 (FIG. 13) before proceeding to attempt once again the network link A 140.

Moreover, (as illustrated in table 400 and by arrow 20) if the personal digital assistant 100 fails to establish the network link A 140, the personal digital assistant 100 attempts again to establish the network link B 150 based on the alternative network link designation 140A, since the network link B 150 is the respective alternative network link for the network link A 140. The personal digital assistant 100 can display the message 900 (FIG. 13) before proceeding to attempt once again the network link B 150. The first loop implementation can continue in a manner illustrated in tables 200, 300, and 400.

Moreover, the personal digital assistant 100 proceeds in a similar manner in the case where the requested network link is the network link B 150, the network link C 160, or the network link D 170.

FIG. 12 illustrates operation of a second loop implementation for attempting multiple network links in accordance with an embodiment of the present invention. For example,

12

(as illustrated in table 500) in the case where the requested network link is the network link A 240, if the personal digital assistant 100 fails to establish the network link A 240, the personal digital assistant 100 attempts to establish the network link C 260 based on the alternative network link designation 240A.

In an embodiment, the personal digital assistant 100 provides a message 900 (FIG. 13) to the user before proceeding to attempt the network link C 260.

Continuing, (as illustrated in table 600 and by arrow 110) if the personal digital assistant 100 fails to establish the network link C 260, the personal digital assistant 100 attempts to establish the network link D 270 based on the alternative network link designation 260A, since the network link D 270 is the respective alternative network link for the network link C 260. The personal digital assistant 100 can display the message 900 (FIG. 13) before proceeding to attempt the network link C 260.

Moreover, (as illustrated in table 700 and by arrow 120) if the personal digital assistant 100 fails to establish the network link D 270, the personal digital assistant 100 attempts again to establish the network link A 240 based on the alternative network link designation 270A, since the network link A 240 is the respective alternative network link for the network link D 270. The personal digital assistant 100 can display the message 900 (FIG. 13) before proceeding to attempt once again the network link A 240. The second loop implementation can continue in a manner illustrated in tables 500, 600, and 700.

Moreover, the personal digital assistant 100 proceeds in a similar manner in the case where the requested network link is the network link B 250, the network link C 260, or the network link D 270.

FIG. 14 illustrates a flow chart showing a method 1000 of enabling a user to provide the alternative network link designations for the network links supported by a personal digital assistant 100 in accordance with an embodiment of the present invention.

At step 1005, the method 100 in accordance with an embodiment of the present invention begins.

Continuing, at step 1010, each network link supported by the personal digital assistant 100 is appropriately configured in the personal digital assistant 100 so that the personal digital assistant 100 can initiate and establish the network link when requested by an application or the user. For example, a network link set-up application can be invoked to configure each network link. The network link set-up process includes: identifying the type of network link, inputting network protocol values, and providing any other information (e.g., type of modem, number to be dialed by a wired or wireless modem, initialization string, etc.) to enable the personal digital assistant 100 to initiate and establish the network link.

At step 1015, the user designates one or several alternative network links for a network link supported by the personal digital assistant 100, whereas the alternative network link is selected from the plurality of network links that the personal digital assistant 100 is configured to support. Also, the user can specify whether the personal digital assistant 100 proceeds as described with respect to FIG. 9 (i.e., chain implementation), as described with respect to FIG. 11 (i.e., first loop implementation), or as described with respect to FIG. 12 (i.e., second loop implementation). The user can omit providing an alternative network link for some of the network links supported by the personal digital assistant 100. Moreover, the user can designate any number of alternative network links for any of the network links supported by the personal digital assistant 100. Additionally, each network link and its corre-

sponding alternative network link designation are associated such that if the network link cannot be established, the personal digital assistant **100** attempts to establish another network link based on the alternative network link designation. In an embodiment, the alternative network link designation is a user-defined preference property stored with the configuration information of the corresponding network link.

At step **1020**, the method **1000** ends.

FIG. **15** illustrates a flow chart showing a method **1200** of establishing a network link on a personal digital assistant **100** in accordance with an embodiment of the present invention. Reference is made to FIGS. **8-13**.

At step **1205**, the method **1200** in accordance with an embodiment of the present invention begins.

Continuing, at step **1210**, an application on the personal digital assistant **100** opens the network library (described with respect to FIG. **8**), whereas the network library has network open code that interfaces with the operating system to initiate and establish a requested network link.

Furthermore, at step **1215**, the application sends a network open request to the network library so that the requested network link is initiated. At step **1220**, the network library receives the network open request.

At step **1225**, the personal digital assistant **100** attempts to establish the requested network link. The personal digital assistant **100** initiates the requested network link by performing the network interface tasks (e.g., powering the modem, instructing the modem to dial a particular number, performing a handshake routine, etc.) that are required for the requested network link.

Moreover, at step **1230**, the personal digital assistant **100** determines whether an error message was generated due to any of a variety of reasons (e.g., a network-related error, a time out error, a non-fatal operating system error), preventing the network link from being established. If the error message was not generated, the personal digital assistant **100** completes establishing the network link and the method **1200** proceeds to step **1255**.

Otherwise, the method **1200** proceeds to step **1235**. At step **1235**, the personal digital assistant **100** determines the appropriate alternative network link designation based on the chain implementation, first loop implementation, or second loop implementation. In an embodiment, the network library receives the error message and determines the alternative network link designation corresponding to the network link. If the network link does not have an alternative network link designation or if there is no additional alternative network link, the method **1200** proceeds to step **1255**.

Otherwise, the method **1200** proceeds to step **1240**. At step **1240**, the personal digital assistant **100** informs the user that the requested network link cannot be established and that another network link will be attempted based on the alternative network link designation. In an embodiment, the message **900** (FIG. **13**) is displayed, allowing the user to prevent the personal digital assistant **100** from proceeding to the alternative network link. Alternatively, the personal digital assistant **100** can proceed to the alternative network link without informing the user that the requested network link could not be established.

At step **1245**, the personal digital assistant **100** determines whether the user desires the personal digital assistant **100** to continue to the alternative network link. If the user does not want the personal digital assistant **100** to continue to the alternative network link, the method proceeds to step **1255** and ends.

Otherwise, at step **1250**, the personal digital assistant **100** attempts to establish another network link based on the alter-

native network link designation. The personal digital assistant **100** initiates the network link by performing the network interface tasks (e.g., powering the modem, instructing the modem to dial a particular number, performing a handshake routine, etc.) that are required for the network link. The method **1200** then proceeds to step **1230**.

Those skilled in the art will recognize that portions of the present invention may be incorporated as computer instructions stored as computer program code on a computer-readable medium such as a magnetic disk, CD-ROM, and other media common in the art or that may yet be developed.

Finally, aspects of the present invention can be implemented as an application, namely, a set of instructions (e.g., program code) which may, for example, be resident in the random access memory of a computer system. Until required by the computer system, the set of instructions may be stored in another computer memory, for example, in a hard drive, or in a removable memory such as an optical disk (for eventual use in a CD-ROM) or floppy disk (for eventual use in a floppy disk drive), or downloaded via the Internet or other computer network. In addition, although the various methods of the present invention described above can be conveniently implemented in a computer system selectively activated or reconfigured by software, one of ordinary skill in the art would also recognize that such methods of the present invention may be carried out in hardware, firmware, or in a more specialized apparatus constructed to perform the required methods of the present invention.

The foregoing descriptions of specific embodiments of the present invention have been presented for purposes of illustration and description. They are not intended to be exhaustive or to limit the invention to the precise forms disclosed, and obviously many modifications and variations are possible in light of the above teaching. The embodiments were chosen and described in order to best explain the principles of the invention and its practical application, to thereby enable others skilled in the art to best utilize the invention and various embodiments with various modifications as are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the Claims appended hereto and their equivalents.

What is claimed is:

1. A method of establishing one of a plurality of network links of a plurality of protocols and diverse types of connection on an electronic system, comprising the steps of:
 - a) associating one or more alternative network link designations with one or more of said network links based upon a priority order assigned by the user of said electronic system and residing on said electronic system;
 - b) requesting a first network link of said plurality of network links;
 - c) attempting to initiate said first network link;
 - d) determining whether a particular alternative network link designation is associated with said first network link; and
 - e) if said step c) fails to establish said first network link and if said particular alternative network link designation is associated with said first network link, attempting to initiate, by said electronic system, a particular network link of said plurality of network links based on said particular alternative network link designation.
2. A method as recited in claim 1, further comprising the steps of:
 - f) determining whether a second alternative network link designation is associated with said particular network link; and

15

- g) if said step e) fails to establish said particular network link and if said second alternative network link designation is associated with said particular network link, initiating a second network link of said plurality of network links based on said second alternative network link designation. 5
3. A method as recited in claim 1, further comprising the step of:
- f) if said step e) fails to establish said particular network link, attempting to initiate, by said computer system, said first network link. 10
4. A method as recited in claim 1, further comprising the step of:
- f) if said step e) fails to establish said particular network link, initiating a second network link of said plurality of network links based on said alternative network link designation. 15
5. A method as recited in claim 1, further comprising the steps of:
- indicating to a user whether said first network link was established; and 20
- enabling said user to discontinue establishment of said particular network link.
6. A method as recited in claim 1, wherein said step b) includes: 25
- sending a network open request to a shared library of said computer system.
7. A method as recited in claim 1, wherein said computer system comprises a personal digital assistant.
8. The method as recited in claim 1, wherein said request for said first network link is based on said priority order. 30
9. A computer-readable medium comprising computer-executable instructions stored therein for performing a method of establishing one of a plurality of network links of a plurality of protocols and diverse types of connection on an electronic system, comprising the steps of: 35
- a) associating one or more alternative network link designations with one or more of said network links based upon a priority order assigned by the user of said electronic system and stored on the electronic system; 40
- b) requesting a first network link of said plurality of network links;
- c) attempting to initiate said first network link;
- d) determining whether a particular alternative network link designation is associated with said first network link; and 45
- e) if said step c) fails to establish said first network link and if said particular alternative network link designation is associated with said first network link, attempting to initiate, by said computer system, a particular network link of said plurality of network links based on said particular alternative network link designation. 50
10. A computer-readable medium as recited in claim 9, wherein said method further comprises the steps of:
- f) determining whether a second alternative network link designation is associated with said particular network link; and 55
- g) if said step e) fails to establish said particular network link and if said second alternative network link designation is associated with said particular network link, initiating a second network link of said plurality of network links based on said second alternative network link designation. 60
11. A computer-readable medium as recited in claim 9, wherein said method further comprises the step of: 65
- f) if said step e) fails to establish said particular network link, attempting to initiate said first network link.

16

12. A computer-readable medium as recited in claim 9, wherein said method further comprises the step of:
- f) if said step e) fails to establish said particular network link, initiating a second network link of said plurality of network links based on said alternative network link designation.
13. A computer-readable medium as recited in claim 9, wherein said method further comprises the steps of:
- indicating to a user whether said first network link was established; and
- enabling said user to discontinue establishment of said particular network link.
14. A computer-readable medium as recited in claim 9, wherein said step b) includes:
- sending a network open request to a shared library of said computer system.
15. A computer-readable medium as recited in claim 9, wherein said computer system comprises a personal digital assistant.
16. The computer readable medium as recited in claim 9, wherein said request for said first network link is based on said priority order.
17. An electronic system comprising:
- a data bus;
- a processor coupled to said data bus; and
- a memory device coupled to said data bus and having computer-executable instructions stored therein for performing a method of establishing one of a plurality of network links of a plurality of protocols and diverse types of connection on said electronic system, comprising the steps of:
- a) associating one or more alternative network link designations with one or more of said network links based upon a priority order assigned by the user of said electronic system and stored on the memory device;
- b) requesting a first network link of said plurality of network links;
- c) attempting to initiate said first network link;
- d) determining whether a particular alternative network link designation is associated with said first network link; and
- e) if said step c) fails to establish said first network link and if said particular alternative network link designation is associated with said first network link, attempting to initiate, by said computer system, a particular network link of said plurality of network links based on said particular alternative network link designation.
18. An electronic system as recited in claim 17, wherein said method further comprises the steps of:
- f) determining whether a second alternative network link designation is associated with said particular network link; and
- g) if said step e) fails to establish said particular network link and if said second alternative network link designation is associated with said particular network link, initiating a second network link of said plurality of network links based on said second alternative network link designation.
19. An electronic system as recited in claim 15, wherein said method further comprises the step of:
- f) if said step e) fails to establish said particular network link, attempting to initiate, by said computer system, said first network link.
20. An electronic system as recited in claim 17, further comprising the step of:

17

f) if said step e) fails to establish said particular network link, initiating a second network link of said plurality of network links based on said alternative network link designation.

21. An electronic system as recited in claim 17, wherein said method further comprises the steps of:

indicating to a user whether said first network link was established; and enabling said user to discontinue establishment of said particular network link.

22. An electronic system as recited in claim 17, wherein said step

b) includes:

sending a network open request to a shared library of said computer system.

23. An electronic system as recited in claim 17, wherein said computer system comprises a personal digital assistant.

24. The electronic system as recited in claim 17, wherein said request for said first network link is based on said priority order.

25. An electronic system comprising;

a data bus;

a memory device coupled to said data bus; and

a processor coupled to said data bus, wherein the processor is configured to attempt to initiate a first network link of a plurality of network links of a plurality of protocols and diverse types of connection in response to a request

18

for said first network link based upon a priority order assigned by the user of said electronic system and stored on the computer system, and wherein if said first network link is not established and if a user has previously designated an alternative network link for said first network link, said processor is further configured to attempt to initiate said alternative network link.

26. An electronic system as recited in claim 25, wherein if said alternative network link is not established, a second alternative network link previously designated by said user is initiated, based on said priority.

27. An electronic system as recited in claim 25, wherein if said alternative network link is not established, said first network link is initiated.

28. An electronic system as recited in claim 25, wherein whether said first network link was established is indicated to said user, and wherein said user is enabled to discontinue establishment of said alternative network link.

29. An electronic system as recited in claim 25, wherein said request is sent to a shared library of said computer system.

30. An electronic system as recited in claim 25, wherein said computer system comprises a personal digital assistant.

31. The electronic system as recited in claim 25, wherein said request for said first network link is based on said priority order.

* * * * *
