(57) **ABSTRACT**

Systems and methods for creating music videos synchronized with an audio track are provided. In some embodiments, an audio track may be selected and one or more video takes may be captured while the selected audio track plays. The video takes may be analyzed while they are captured to determine, for example, a video intensity level and/or a number of faces recognized within each take. By capturing the video takes with the audio track, the video takes may be synchronized to the audio tracks so that they are in time with one another. Portions or subsets of the video takes may be paired or matched with certain sections of the audio track based on, for example, the audio characteristics for a particular section and video characteristics of a particular take.

## SYSTEMS AND METHODS FOR CREATING MUSIC VIDEOS SYNCHRONIZED WITH AN AUDIO TRACK

### FIELD OF THE INVENTION

Various embodiments described herein generally relate to systems and methods for creating music videos. In particular, music videos may be created including portions of one or more video takes that are automatically synchronized to an audio track.

### BACKGROUND OF THE INVENTION

Music videos, whether they involve famous musicians or independent artists, are fun and creative mediums for sharing one's music and musical style with the world. While most music videos, at least historically, were created in support of established musicians for marketing purposes, the enhanced capabilities of mobile devices allows almost any individual to record and edit music, as well as capture video, all using one device. Individuals, whether an experienced musician or a novice, young or old, now have the ability to create their own music videos using such devices.

Although music videos often include an individual's own music, it is also possible for music videos to be created based on an individual's favorite or a popular song. While there are presently some applications of this concept, most of these applications have several inherent drawbacks.

In one instance, music videos have been created where an audio track plays in the background while a single video is captured or recorded. This, however, creates an extremely poor quality music video as there is no visual transition between various parts of the audio track. For example, a single video take may be used for the audio track's verse and chorus. This leads to extremely unprofessional looking music videos that, while potentially entertaining, are aesthetically inferior to professional quality music videos, which may use multiple video takes captured at one or more locations.

Another instance of music videos being created focuses on a linear application of a video and audio track. For example, a single video take may be captured and multiple end points may be applied to that video. However, this application is extremely limited in that it does not allow a user to use multiple video, and, as such, does not allow the user to apply multiple end points to the multiple videos. Furthermore, in order to have different locations in the music video, a user would need to visit multiple locations in chronological order and capture video at each location. The editing of the video takes captured at each location would then only present the locations in the order that they were visited. This, as mentioned previously, creates a music video that is unprofessional in appearance, as professional music videos may have varying locations throughout the music video.

In another, somewhat similar, instance, music videos have been created where a user is required to capture video of another individual within a silhouette. A generic silhouette is overlaid on the user's display and, while the user records video, the individual being recorded must stay generally within the bounds of the silhouette. While this may expand the manipulative aspects of the video, the user is unfortunately constrained to be within one particular area, and does not have a free range of motion to fully capture any desired action. Furthermore, as the user is bound by the silhouette,

2

the ability to transition to different video takes for different portions of an audio track is limited, if at all possible.

In yet another instance, music videos have been created that include only a small portion or snippet of the audio track with an individual capturing a single video for that portion of the audio track. For example, a user may select a song to form a music video for, and create a music video based on the song's verse or chorus. This may lead to short, dull, and unprofessional music videos as the music video may become nothing more than a video clip for a small tidbit of a song.

Thus, in light of some of the aforementioned problems, it would be beneficial for there to be systems, methods, and non-transitory computer readable mediums that allow a user to create a professional style music video using portions of multiple videos taken at different times and at different locations that are automatically synchronized to a selected audio track. Furthermore, it would be beneficial for there to be systems, methods, and non-transitory computer readable medium that allow video takes to be paired with an audio track such that sections of the audio track having various intensity levels or dynamics are matched with suitable portions of the video takes.

### SUMMARY OF THE INVENTION

This generally relates to systems, methods, and non-transitory computer readable mediums for creating music videos that are synchronized to an audio track.

In one exemplary embodiment, a method for creating a music video where an audio track is synchronized with a plurality of video takes is described. An audio track, such as a song, may be selected. For example, a user may select a song stored on their user device, in a music library on an external device, or on a music server. A plurality of video takes may be captured also using the user device. While the plurality of video takes are being captured, they may also be synchronized with the selected audio track. The synchronization allows for the captured video takes to be aesthetically and/or musically synchronized with an appropriate section or sections of the audio track. A music video may then be created including the audio track and at least a subset of the plurality of video takes that are already synchronized to the selected audio tracks. For example, portions of one or more captured video takes may be matched to certain sections of the audio track based on the audio track's audio intensity levels and/or a particular video take's video intensity.

In another exemplary embodiment, a user device including at least one audio input component, at least image capturing component, memory, and at least one processor is described. The memory may store an audio track recorded using the at least one audio input component and a plurality of video takes captured by the at least one image capturing component. For example, a user may record an audio track using their user device's microphone as well as record video takes using one or more cameras resident on the user device. The at least one processor of the user device may then determine a vocal and/or melodic phrase within the recorded audio track, and synchronize at least a portion of one or more captured video takes to the recorded audio track based on the determined vocal and/or melodic phrase while the at least one of the plurality of video takes is captured.

In yet another exemplary embodiment, another method for creating a music video is described. An audio track may be selected and a plurality of video takes may be captured. A number of faces within each video take of the captured video takes may be determined while the plurality of video takes are being captured. Also while the plurality of video

takes are being captured, at least a subset of the plurality of captured video takes may be synchronized to the selected audio track based on the number of faces determined to be within each video take. A music video may then be created including the selected audio track and at least the subset of the plurality of captured video takes synchronized to the selected audio track.

In still yet another exemplary embodiment, a user device including memory for storing a plurality of video takes, at least one image capturing component, and at least one processor is described. The at least one processor is operable to receive a selection of an audio track from the plurality of audio tracks stored in memory. The audio track may then play and, while playing, at least one video take may be captured using the at least one image capturing component. The at least one captured video take may be synchronized to the selected audio track while the selected audio track plays. A music video may then be generated that includes the selected audio track and at least a subset of the at least one video take that is already synchronized to the selected audio track.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The above and other features of the present invention, its nature and various advantages will be more apparent upon consideration of the following detailed description, taken in conjunction with the accompanying drawings in which:

FIG. 1 is an illustrative block diagram of a user device in accordance with various embodiments;

FIG. 2 is an illustrative diagram of a user interface displayed on a user device in accordance with various embodiments;

FIGS. 3A and 3B are illustrative diagrams of user interfaces displayed on a user device for selecting an audio track in accordance with various embodiments;

FIG. 4 is an illustrative diagram of a user interface displayed on a user device presenting a selected audio track for a music video to be created in accordance with various embodiments;

FIGS. 5A and 5B are illustrative diagrams of various user interfaces displayed on a user device for capturing video takes for a music video to be created in accordance with various embodiments;

FIGS. 6A-C are illustrative diagrams of various user interfaces displaying video takes being captured by a user device for a music video in accordance with various embodiments;

FIGS. 7A and 7B are illustrative diagrams of a created music video including a plurality of captured video takes synchronized to selected audio track in accordance with various embodiments;

FIGS. 8A and 8B is an illustrative flowchart of a process for creating music videos in accordance with various embodiments;

FIGS. 9A-C are illustrative diagrams of user interfaces including various video takes having a number of faces or images determined to be within the video takes in accordance with various embodiments;

FIG. 9D is an illustrative diagram of various sections of a selected audio track's waveform synchronized with portions of video takes based on the number of faces determined to be within each video take in accordance with various embodiments;

FIG. 9E is an illustrative flowchart of a process for synchronizing video takes to an audio track based on a

number of faces determined to be within the video takes in accordance with various embodiments;

FIGS. 10A-D are illustrative diagrams of various vocal and melodic indicators and phrases for use as transition points between video takes for a music video synchronized to an audio track in accordance with various embodiments;

FIG. 10E is an illustrative flowchart of a process for creating a music video including various video takes synchronized to a recorded audio track based on a determined vocal and/or melodic phrase within the audio track in accordance with various embodiments; and

FIG. 11 is an illustrative diagram of a user interface for recording an audio track to be used for creating a music video in accordance with various embodiments.

#### DETAILED DESCRIPTION OF THE INVENTION

The present invention may take form in various components and arrangements of components, and in various techniques, methods, or procedures and arrangements of steps. The referenced drawings are only for the purpose of illustrated embodiments, and are not to be construed as limiting the present invention. Various inventive features are described below that can each be used independently of one another or in combination with other features. Furthermore, in at least some embodiments, like referenced numerals refer to like parts throughout.

FIG. 1 is an illustrative block diagram of a user device in accordance with various embodiments. User device 100, in some embodiments, may correspond to any electronic device or system. Various types of user devices include, but are not limited to, portable media players, cellular telephones or smart phones, pocket-sized personal computers, personal digital assistants ("PDAs"), desktop computers, laptop computers, tablet computers, and/or electronic accessory devices such as smart watches and bracelets. User device 100 may communicate with one or more additional user devices, networks, and/or servers. For example, user device 100 may send text messages to other user devices across a network, or user device 100 may access one or more websites located on a server.

User device 100, in some embodiments, may include one or more processors 102, memory 104, storage 106, communications circuitry 108, an input interface 110, and an output interface 118. In some embodiments, input interface 110 may include one or more cameras 110 or other image capturing components, one or more microphones 112 or other audio capturing components, and one or more external device inputs 116. Further, in some embodiments, output interface 118 may include display 120 and one or more speakers 122 or other audio output components. Persons of ordinary skill in the art will recognize that user device 100 may include any number of components, and one or more additional components or modules may be added or omitted without deviating from the scope of the present disclosure. Additionally, one or more components may be combined or separated, and multiple instances of various components are also possible, however only one of each component is shown within user device 100 for simplicity.

Processor(s) 102 may include any suitable processing circuitry, such as one or more processors, capable of controlling the operations and functionality of user device 100. In some embodiments, processor(s) 102 may facilitate communications between various components within user device 100. For example, processor(s) 102 may cause output interface 118 to perform an associated output in response to

one or more inputs being detected by input interface **110**. Processor(s) **102** may run an operating system for user device **100**, applications resident on user device **100**, firmware applications, media application, and/or any other type of application, or any combination thereof function on, or in conjunction with, user device **100**.

Memory **104** may include any suitable form of memory, such as cache memory, semi-permanent memory (e.g., RAM), or any other memory type, or any combination of. In some embodiments, memory **104** may be used in place of and/or in addition to an external memory or storage unit or device for storing data on user device **100**.

Storage **106** may include one or more storage mediums. Various types of storage mediums include, but are not limited to, hard drives, solid state drives, flash memory, permanent memory (e.g., ROM), or any other storage type, or any combination thereof. Any form of data or content may be stored within storage **106**, such as photographs, music files, videos, contact information, applications, documents, or any other file type, or any combination thereof.

In some embodiments, memory **104** and storage **106** may be combined into a single component. For example, a single memory component may include memory and storage functions. In other embodiments, multiple instances of memory **104** and/or storage **106** may be present, however it is also possible for memory **104** and/or storage **106** to be external to user device **100**. For example, one or more files may be stored remotely on an external hard drive or on a cloud storage provider. However, persons of ordinary skill in the art will recognize that the aforementioned scenarios are merely examples.

Communications circuitry **108** may include any circuitry capable of connecting user device **100** to one or more additional devices (e.g., laptop computers, smartphones, etc.), one or more networks (e.g., local area networks (“LAN”), wide area networks (“WAN”), point-to-point networks, etc.), and/or one or more servers (e.g., file management systems, music directories, etc.). Communications circuitry may support any suitable communications protocol including, but not limited to, Wi-Fi (e.g., 802.11 protocol), Bluetooth®, radio frequency systems (e.g., 900 MHz, 1.4 GHz, and 5.6 GHz communications systems), infrared, GSM, GSM plus EDGE, CDMA, quadband, LTE, VOIP, or any other communications protocol, or any combination thereof.

Input interface **110** may include any suitable mechanism and/or component for receiving inputs from a user operating user device **100**. For example, input interface **110**, in one embodiment, includes one or more cameras **112**. Cameras **112** may correspond to any suitable image capturing component capable of capturing images and/or video. For example, camera **112** may capture photographs, sequences of photographs, rapid shots, videos, or any other type of image, or any combination thereof. In some embodiments, cameras **112** may be capable of capturing high-definition (“HD”), 3-D, and/or panoramic images and/or videos. In some embodiments, cameras **112** may include one or more filters or settings for images and/or video that may be captured by cameras **112** (e.g., black and white, monochromatic, fades, slow-motion, etc.). In some embodiments, user device **100** may include multiple instances of camera **112**. For example, user device **100** may include a front-facing camera and a rear-facing camera. In some embodiments, one or more additional image capturing components, such as a zoom or add on filter, may be used in connection with, or instead of, camera **112** to aid in capturing images and/or videos.

Microphone(s) **114** may be any component capable of detecting and/or receiving audio signals. For example, microphone(s) **114** may include one or more sensors for generating electrical signals and circuitry capable of processing the generated electrical signals. In some embodiments, user device **100** may include multiple instances of microphone **114**, such as a first microphone and a second microphone. In some embodiments, user device **100** may include multiple microphones capable of detecting various frequency levels (e.g., high/low-frequency microphones). Furthermore, in some embodiments, one or more external microphones may be connected to user device **100** and may be used in conjunction with, or instead of, microphone(s) **114**.

External device input **116** may correspond to any input interface or set of input interfaces capable of receiving inputs from an external device. For example, one or more external microphones, as described above, may be coupled to user device **100** through external device input **116**. As another example, a user may couple an electric guitar, drums, and/or keyboard to user device **100** via external device input **116**. However, it is also possible for a user to couple one or more external devices, such as a guitar or keyboard, to an external musical interface (e.g., a mixing board or computer), which in turn may couple to user device **100** via external device input **116**.

Output interface **118** may include any suitable mechanism or component for generating outputs from a user operating user device **100**. For example, display **120** may, in some embodiments, present content to a user on user device **100**. Display **120** may be any size or shape, and may be located on one or more regions/sides of user device **100**. For example, display **120** may fully occupy a first side of user device **100**, or display **120** may only occupy a portion of a first side of user device **100**. Various display types include, but are not limited to, liquid crystal displays (“LCD”), monochrome displays, color graphics adapter (“CGA”) displays, enhanced graphics adapter (“EGA”) displays, variable graphics array (“VGA”) displays, 3-D displays, high-definition (“HD”) displays, or any other display type, or any combination thereof.

In some embodiments, display **120** may be a touch screen and/or an interactive touch sensitive display screen. For example, display **120** may be a multi-touch panel coupled to processor(s) **102**, and may include one or more capacitive sensing panels. In some embodiments, display **120** may also correspond to a component, or portion, of input interface **110**, as it may recognize and one or more touch inputs. For example, in response to detecting certain touch inputs on display **120**, processor(s) **102** may execute one or more functions for user device **100** and/or may display certain content on display **120**.

Speakers **122** may correspond to any suitable mechanism for outputting audio signals. For example, speakers **122** may include one or more speaker units, transducers, or arrays of speakers and/or transducers capable of broadcasting audio signals and/or audio content to an area where user device **100**, or a user, may be located. In some embodiments, speakers **122** may correspond to headphones or ear buds capable of broadcasting audio directly to a user. In yet another embodiment, one or more external speakers may be connected to user device **100** (e.g., via external device input **116**), and may serve to provide audio content to a user associated with user device **100**.

FIG. 2 is an illustrative diagram of a user interface displayed on a user device in accordance with various embodiments. User interface **200**, in some embodiments, is

displayed on a display screen, such as display **120** of user device **100**. User interface **200** may include project button **202**. A user may select project button **202**, in some embodiments, to begin a process of making a music video (described in more detail below).

In some embodiments, user interface **200** may include project section **210** including already formed or started projects **210a** and **210b**. Each of projects **210a** and **210b** include a song title **208**, for which the corresponding project's music video is based on. For example, a user may have previously created a music video based on a song entitled "Song 1". Each project **210a** and **210b** may also include a delete button **206** and an edit button **204**. When a user selects edit button **204** for a particular project, the user may be taken into that project's workspace, and may have the option to edit the project in one or more ways, which will be described in greater detail below. A user may also choose to delete a certain project or projects by selecting delete button **206**. For example, a user may be unsatisfied with a particular music video they created in one of projects **210a** and **210b**, and may choose to delete that project. User interface **200** may also include preview window **212** for each project **210a**, **210b**. Preview window may present a clip or sample of the created music video from each of projects **210a** and **210b** so that a user may see, prior to editing or deleting a particular project, what the music video will look like. This way, a user may be able to familiarize themselves with the music video for a specific project to determine whether or not further edits are needed and/or the music video should be deleted.

FIGS. 3A and 3B are illustrative diagrams of user interfaces displayed on a user device for selecting an audio track in accordance with various embodiments. User interface **300** of FIG. 3A includes audio tracks **302a-g** displayed therein, which are presented in response to a user selecting project button **202** on user interface **200**. Audio tracks **302a-g**, in some embodiments, may be stored locally on user device **100** (e.g., in storage **106**), or externally on an external user device (e.g., a compact disc ("CD"), external hard drive, digital music player), or on a web based storage medium (e.g., a cloud storage system or music server). A user may scroll through all the audio tracks available by scrolling about user interface **300** in either direction of double-sided arrow **306**. For example, audio tracks **302a-g** may be organized alphabetically, thus a user may view audio tracks beginning with a certain letter by scrolling upwards or downwards about a display (e.g., display **120**) presenting user interface **300** to view different audio tracks beginning with different.

User interface **300** may also include one or more additional pieces of information for each audio track such as a duration for each audio track, a genre, an artist name, an album name, or any other relevant information. For example, a user may select a certain audio track based on a time that the audio track lasts. In some embodiments, each audio track includes a selection button **304**. When a user presses selection button **304**, that particular audio track will be selected as the basis for the music video that will be created. For example, as seen in FIG. 3A, a user may select audio track **302b** by pressing selection button **304**.

In some embodiments, in response to selecting an audio track, a user may be able to select a section of the song that the music video will be created for. For example, audio track **302b** may be 3 minutes 36 seconds long. A user may not want to create a music video that is that long, and instead may select, for example, a 1 minute portion of audio track **302b** as a basis for the music video that will be created.

Audio track **302b** may be represented by a waveform **360**, as seen in user interface **350** of FIG. 3B. Waveform **360** may highlight to the user various sections of audio track **302b** and a corresponding audio intensity level for those sections. For example, sections corresponding to an audio track's chorus may be louder than sections corresponding to the audio track's verse. The user may select a starting point for the selected audio track by moving starting bar **362** about waveform **360**. Where the user places starting bar **362** on waveform **360** would then correspond to a beginning of the section of audio track **302b** that would be used for the created music video. Similarly, ending bar **364** may be placed at any point on waveform **360**, and would correspond to an end of the section of audio track **302b** to be used for the created music video. In some embodiments, beginning bar **362** and ending bar **364** may initially be located at the beginning and end, respectively, of audio track **302b**. In this particular scenario, the user may choose to not move beginning and end bars **362** and **364**, in which case the selected portion of audio track **302b** used for creating the music video would be the entire audio track.

FIG. 4 is an illustrative diagram of a user interface displayed on a user device presenting a selected audio track for a music video to be created in accordance with various embodiments. User interface **400**, in some embodiments, may include a listing of audio tracks that have been selected by a user to be used for a music video that will be created. For example, a user may select an audio track, such as audio track **302b** of FIG. 3A, and that audio track may be displayed within user interface **400** at listing **402**. In response to selecting audio track **302b**, in some embodiments, various statistics may be extracted from selected audio track **302b** (or any other audio track that is selected) when it is loaded into listing **402**. For example, a distribution, mean, skew, or any other statistic, or any combination thereof, may be extracted from the audio track in order to be used while creating the music video for the selected audio track.

User interface **400** may also include return or back button **404**, which may allow a user to return back to user interface **300** or **350**. In some embodiments, a user may wish to select a different audio track from audio tracks **302a-g**, and may use back button **404** to select a different audio track. For example, initially a user may have selected audio track **302b**, however at a latter point in time, the user may decide that he/she wants to use audio track **302f**, and may use back button **404** to return to user interface **300** to select audio track **302f**. In some embodiments, a user may seek to modify a duration of the audio track they selected. For example, in user interface **350** of FIG. 3B, a user may have selected beginning bar **362** to be at a first position and ending bar **364** to be at a second position. At a latter point in time, however, the user may decide that the duration of the selected audio track from the first position to the second position is not correct and, by selecting back button **404**, may return to user interface **350** to modify a position of beginning bar **362** and/or ending bar **364**.

User interface **400** may also include video take button **406** and create music video button **408**. After audio listing **402** has loaded (e.g., one or more statistical values have been extracted from the audio track), a user may select video take button **406** to begin to capture video takes for a music video that will be created based on the selected audio track. After a user has determined that all the video takes for the music video have been captured, the user may select create music video button **408** to create the music video based on the selected audio track and the captured video takes.

FIGS. 5A and 5B are illustrative diagrams of various user interfaces displayed on a user device for capturing video takes for a music video to be created in accordance with various embodiments. User interface 500, in some embodiments, is an exemplary image capturing interface displayed on a user device (e.g., user device 100) in response to a user selecting video take button 406 of FIG. 4. For example, in response to selecting video take button 406 of user interface 400, camera 112 on user device 100 may open or begin operating, and images that may be captured by camera 112 may be displayed within viewing area 506 of user interface 500. In some embodiments, a user may switch between two or more cameras 110 located on their user device by selecting switch camera button 504. For example, if user device 100 includes a front facing camera and a rear facing camera, switch camera button 504 may allow the user to switch between the two.

A user may begin capturing images, such as video, by selecting start button 502. For example, a user may begin to capture video for a music video to be created by first selecting start button 502. In some embodiments, a countdown may appear within viewing area 506 in response to a user selecting start button 502. The countdown may enable the user to ready themselves for the image capturing process to begin. In some embodiments, after a user selects start button 502, the selected audio track (e.g., audio track 302b), may begin to play, and the image capturing process may capture images until the audio track, or selected portion of the audio track, has completed. However, in some embodiments, one or more additional buttons, such as a stop button may be included within user interface 500.

User interface 500 also may include a filter setting 508. Filter setting 508 may correspond to one or more filters or masks for images captured for the music video to be created. In some embodiments, a user may perform one or more gestures to switch between different filter types. For example, a user may swipe across a display screen of their user device display user interface 500 to have a different filter applied.

User interface 550 of FIG. 5B corresponds to a user interface displayed on a user device having a different filter than user interface 500 of FIG. 5A. For example, in response to performing a swipe across a display screen, user interface 500 may change to user interface 550 corresponding to filter setting 508 changing to filter setting 518. Any number of filters may be used in conjunction with user interfaces 500 and 550, and the aforementioned are merely exemplary. Images captured while having filter setting 518 applied may differ from similar images captured while filter setting 508 is applied in that the formatting, shading, masking, lighting, or other features, may differ for various filters. However, persons of ordinary skill in the art will recognize that any filter may be applied to any image.

FIGS. 6A-C are illustrative diagrams of various user interfaces displaying images being captured by a user device for a music video in accordance with various embodiments. User interfaces 600, 620, and 640, in one embodiment, each include capture button 602 and viewing area 606. Capture button 602 may, for example, be substantially similar to start button 502 of FIGS. 5A and 5B, with the exception that capture button 602 may also be used to stop or pause an image capturing session. Viewing area 606, in some embodiments, includes any images that can or will be captured by the user device in response to the image capturing session beginning.

User interfaces 600, 620, and 640 may also, in some embodiments, include waveform 660, which corresponds to

a waveform of a selected audio track that may be playing while a user captures one or more images during the image capturing session. For example, in response to beginning an image capturing session, the selected audio track (e.g., from FIGS. 3A and 3B), may begin to play. Position bar 618 of user interface 600 may show a current position of the selected audio track as it plays. As an audio track progresses, position bar 618 will move to various positions along waveform 660 to indicate a current position within the audio track. User interface 620 includes position bar 628 which may show a current position of the selected audio track shown by waveform 660, where position bar 628 is different than position bar 618 in that they correspond to two different times within the selected audio track and/or different video takes. Similarly, user interface 640 includes position bar 648 which depicts yet another time within the selected audio track and/or yet another video take.

By having the audio track playing while the various video takes are captured, the video takes may be captured “in sync” with the audio track. For example, at each moment of a video take, a corresponding section of the audio track that may be playing at that point in time will be known. This way, each video take, whether it begins at the beginning of the audio track or at some other point of the audio track, will be synchronized to the audio track.

In some embodiments, user interface 600 may also include a timer 614 and a video take indicator 612. Timer 614 may indicate an amount of time that an image capturing session has been active. For example, in response to an image capturing session beginning, such as by pressing start button 502 or capture button 602, timer 614 may begin to time how long the image capturing session has been going. In some embodiments, time 614 may indicate where position bar 618 is within waveform 660. For example, if the image capturing session begins at the beginning of the audio track and ends at the end of the audio track, then timer 614 may correspond to an amount of time that the audio track has been playing, and thus, the amount of time the image capturing session has been active. Video take indicator 612, in some embodiments, may indicate to a user which video take the user is currently on. For example, as seen in FIG. 6A, video take indicator 612 may indicate to the user that the images being captured by their user device in the current image capturing session, “Take 1”, is a first video take. After the first video take is complete, the next time the user starts a video capturing session for a music video project, the video indicator will show a different value for video take indicator 612. For example, video take indicator 626 of FIG. 6B, indicates to the user that the images being captured in user interface 620 corresponds to a second video take, “Take 2”. Furthermore, images captured in yet another image capturing session may indicate to the user that it is a third take, as seen by video take indicator 646 of FIG. 6C displaying “Take 3” within user interface 640.

In some embodiments, each video take may correspond to a different image, set of images, and/or video for a different environment or action for the selected audio track’s music video. For example, in Take 1 (e.g., user interface 600), a user may capture images of a friend dancing to the selected audio track. Take 2 (e.g., user interface 620), however, may capture images of a different friend or friends, or the same friend, as Take 1, however he/she/they may be performing a different action. Take 3 (e.g., user interface 640) may correspond to a completely different action or group of images for the music video, for example, images of a river or brook. Persons of ordinary skill in the art will recognize

that any number of takes may be captured for a particular music video, and the images captured may include any suitable content.

FIGS. 7A and 7B are illustrative diagrams of a created music video including a plurality of captured video takes synchronized to a selected audio track in accordance with various embodiments. Music video **700**, in one embodiment, is an exemplary break-down of a music video in a time-line or story board type format. As a video itself is difficult to reproduce pictorially, music video **700** is an exemplary description of various “scenes” or portions of a music video that are created based on an audio track (e.g., audio track **302b** of FIG. 3A), laid out such that sections of the selected audio track and their corresponding video take portions are shown paired together. However, persons of ordinary skill in the art should recognize that this is merely an exemplary reconstruction of continuous images (e.g., video), and the description presented herein is merely for illustrative purposes.

Scenes or portions **710**, **720**, **730**, **740**, **750**, **770**, **780**, and **790** of video **700** correspond to certain images or video captured by a user while in an image capturing session (e.g., FIGS. 6A-C). Scene information **712** includes the relevant video take and timing for scene **710**. For example, scene **710** of video **700** includes a portion of Take 3. In particular, the portion of Take 3 (e.g., FIG. 6C) used in scene **710** is times 00:00-00:30 of Take 3, or the first 30 seconds of Take 3. The portion of Take 3 corresponding to time 00:00-00:30 is displayed by images/videos **716**.

As another example, scene **730** includes scene information **732**. Scene information **732** indicates that, in scene **730**, the take that is used is Take 2, and the portion of the captured images or video that is used is from time 00:30-00:50. The portion of Take 2 corresponding to time 00:30-00:50 is displayed in viewing area **736**.

A scene’s images may be matched to an appropriate section of the selected audio track’s waveform **760** (e.g., corresponding to the selected audio track **302b** of FIG. 3A). For example, scene **710** may be synchronized to section **714** of waveform **760**. In some embodiments, an audio intensity of a particular section of the selected audio track for the music video may be used to determine which portion of a particular video take to use. Section **714** of waveform **760**, for example, may correspond to an introduction or instrumental portion of the audio track and therefore may have a lower volume than a section of waveform **760** corresponding to a chorus or crescendo. In some embodiments, based on the audio intensity or level of section **714**, a portion of a video take may be selected to be matched with section **714** to compliment it. For example, Take 3 may include images of a river or brook, and therefore may be matched with section **714** of waveform **760** due to section **714** that is substantially lower in volume than a section of waveform **760** that has a substantially high volume (e.g., a chorus section).

In some embodiments, a random selection of a certain portion of the video takes corresponding to a certain section of the audio track may be used for the music video. For example, if the user captures three video takes (e.g., Take 1, Take 2, and Take 3), for each section of the audio track, a random selection of a portion of one or more of these video takes may be used for that section of the audio track. The selected portion of the video take will be synchronized, in one embodiment, to the section of audio track prior to being selected. In some embodiments, when the music video is created, a first section of the audio track may be matched with a corresponding first portion of Take 1, whereas a

second section of the audio track may be matched with a corresponding second portion of Take 2, and a third section of the audio track may be matched with a corresponding third portion of Take 3. If, however, the user decides to create another music video using the same video takes and audio track, a different ordering and/or portion of the video takes may be used, as they may be randomly selected. For example, if a user selects create music video button **408** of FIG. 4, a music video may be created where the first section of the audio track may be matched with a corresponding first portion of Take 3, the second section of the audio track may be matched with a corresponding second portion of Take 1, and the third section of the audio track may be matched with a corresponding third portion of Take 2.

In some embodiments, if a section of waveform **760** has a particularly high or large audio intensity, a portion of a video take having a particularly high or large video intensity level may be matched with that section. For example, section **784** of waveform **760** may have a substantially high volume (e.g., greater than 80 dB), corresponding to a final chorus or crescendo for the selected audio track. In this particular scenario, scene **780** may include images/video **786** corresponding to image captured of a user moving frequently, singing loudly, dancing intensely, or performing any other action resulting in a high level of video intensity. For example, a frame by frame analysis of images/video **786** may show a substantial change in pixel level for each frame of the video take, indicating that the images displayed therein may be changing rapidly. Scene information **782** may indicate that this particular portion of images/video may correspond to Take 1, and more specifically to times 02:40-03:00 of Take 1.

Another section of waveform **760**, section **744**, may also include a portion of Take 1. As seen by scene information **742**, section **744** may be matched with times 01:00-01:30 of Take 1, shown by images/videos **746**. Section **744** may have a particularly high or large audio intensity, which may match a level of video intensity of Take 1 between times 01:00 and 01:30. Similarly, section **724** of waveform **760** may include times 00:30-00:50 of Take 1 as shown by images/video **726**, as indicated by scene information **722** of scene **720**.

Other sections of waveform **760** include sections **774** and **794**, each of which may correspond to section of waveform **760** having a substantially low or small audio intensity (e.g., low volume (less than 40 dB)), or, a section having a substantially constant or moderate audio intensity. Each of sections **774** and **794** may be matched with a portion of Take 3, as indicated by scene information **772** and **792** of scenes **770** and **790**, respectively. In particular, scene **770** includes times 02:00-02:40 of Take 3, as shown by images/video **776**, and scene **790** includes times 03:00-03:36 of Take 3, as shown by images/video **796**.

Sections of waveform **760** that have a substantially medium level of audio intensity may include portions of Take 2, in some embodiments. For example, sections **734** and **754** may correspond to a verse of a particular audio track for waveform **760**. Based on the audio intensity of sections **734** and **754**, images/videos **736** and **756** of scenes **730** and **750** may be matched with sections **734** and **754** based on a similar level of video intensity included therein. For example, as indicated by scene indicators **732** and **752** of scenes **730** and **750**, images/videos **736** and **756** of scenes **730** and **750** correspond to times 00:50-01:00 and 01:30-02:30 of Take 2, respectively.

In some embodiments, a time or duration of each portion of selected images/video may be equal to the corresponding section of waveform **760** that it has been synchronized to.

13

For example, section 774 of waveform 760 begins at time 02:00 and ends at time 02:40. Thus, the portion of Take 3 shown within scene 770 is also equal to a 40 second time period, as indicated by scene information 772. Similarly, section 734 of waveform 760 begins at time 00:50 and ends at time 01:00. Correspondingly, Take 2 of scene 730 is paired such that 10 seconds of Take 2 are used (e.g., times 00:50-01:00). Persons of ordinary skill in the art will recognize that any amount of time for any section of audio or portion video may be used, and the illustrated time periods are merely exemplary. Furthermore, any suitable criteria for synchronizing certain sections of audio with certain portions of video/images may be used, and use of audio intensity and video intensity levels are merely one illustrative example. Still further, any number of sections of a waveform of a selected audio track may exist or be formed, and the illustrated sections of waveform 760 are merely one particular example.

In some embodiments, a user unsatisfied with a particular scene of music video 700 may change the video take chosen for a particular scene by providing one or more gestures to the user device displaying the music video. For example, a user unhappy with Take 3 being used for scene 770 may swipe up on the display screen displaying music video 700 at section 774 to cause the selected video take to be changed. In response to swiping up on the display screen, scene 770 may change from using Take 3, to now using Take 1 or 2, for example, at times 02:00-02:40. Persons of ordinary skill in the art will recognize that any gesture may be used, and the aforementioned is merely exemplary. For example, a swipe, flick, click, tap, or sweeping gesture, or any other suitable gesture may be used to change a video take used, and the aforementioned is merely exemplary.

FIG. 7B is an illustrative block diagram of music video 700 of FIG. 7A in accordance with various embodiments. Block diagram 702 of music video 700 describes how portions of various video takes are used to form music video 700. In some embodiments, block diagram 702 may include three video takes—Take 1, Take 2, and Take 3. For example, a user may capture each video take at a different location and the captured images may differ for each video take. In the illustrative example, each video take may also be of equal duration as an audio track, such as a selected audio track used for waveform 760.

In some embodiments, a darkened portion of block diagram 702 may correspond to portions of a video take used when music video 700 is created. An unused portion of a video take may, subsequently, correspond to a white or empty portion of block diagram 702. In the non-limiting illustrative embodiment, block diagram 702 for music video 700 may have a portion of Take 1 used at a beginning of the created music video, which may be followed by a portion of Take 2, and then a portion of Take 3. As seen in diagram 702, when a portion of one video take is used, a portion of the other video takes corresponding to a same section of the audio track, is unused. Thus, when a portion of Take 1 is used at the beginning of the music video, portions of Takes 2 and 3 for that same section of the audio track are unused. This allows music video 700 to be created such that a continuous music video, having portions of different video takes, which may be captured at various times and at various locations, are paired together to create a professional and aesthetically unique music video.

FIG. 8A is an illustrative flowchart of a process for creating music videos in accordance with various embodiments. Process 800 may begin at step 802. At step 802, an audio track may be selected. For example, a user may select

14

an audio track stored on their user device to be used as a basis for creating a music video. As another example, the selected audio track may be stored on an external device, such as an external hard drive, CD, or digital music player, or the audio track may be stored on a cloud storage system, such as a music server. However, in one embodiment, an audio track may be created by a user using their user device (as described in greater detail below with regards to FIG. 11), and the created audio track may be used to create a music video.

Process 800 may then proceed to step 804. At step 804, a duration may be selected for the audio track selected at step 802. For example, a user may decide to only include a portion of the selected audio track for the music video that will be created. The user may, in one particular instance, move a beginning bar 362 of FIG. 3B to a first or starting position for the selected audio track, and then move ending bar 364 to a second or end position for the selected audio track. As another example, a user may decide to only include a chorus section of an audio track for a music video that will be created. A user may modify a start point and end point for the particular audio track such that the audio track begins at the start of the chorus and ends at the end of the chorus. As yet another example, step 804 of process 800 may be omitted in some embodiments. For this particular scenario, the duration of the selected audio track may default to the entire audio track's duration, and the user may not be required to select a beginning or end to the audio track for the music video. In some embodiments, step 804 may be skipped or omitted and the duration of the selected audio track may default to be the entire duration of the audio track.

At step 806, a video take may be captured while the selected audio track plays. In some embodiments, in response to selecting the audio track and/or in response to selecting a duration for an audio track (e.g., steps 802 and/or 804), an option to capture a video take may be presented to a user. A user may select the capture video take option to begin to capture video for a music video to be created based on the selected audio track. For example, a user may select start button 502 of FIGS. 5A and 5B, or capture button 602 of FIGS. 6A-C to begin to capturing video takes. In some embodiments, a user may perform one or more gestures, such as a swipe across a displayed user interface, to cause a filter or mask to be applied to the captured video. For example, filter settings 518 may be applied to captured images, as displayed in viewing region 506 of FIG. 5B, in response to a user performing an action on user interface 500 having normal filter setting 508 (e.g., no filter).

As a user begins to capture video for a video take, the selected audio track, or selected section of the audio track selected, may begin playing. For example, after a user selects capture button 602 of FIG. 6A, the selected audio track may begin to play. In some embodiments, by playing the selected audio track while a video take is captured, that video take may be synchronized with the audio track automatically. For example, each moment of the captured video take may be synchronized to a corresponding section of the selected audio track, as the video take is captured in time with the audio track as it plays. In some embodiments, a position indicator 618 may indicate a current position of the audio track playing while the video take is being captured. The audio track may output through a user device's speakers, such as speakers 122, while one or more cameras 112 capture the video take.

Process 800 then proceeds to step 808. At step 808, a determination is made as to whether or not the user is finished capturing video takes. If, at step 808, it is deter-

mined that the user is not finished capturing video takes for the music video to be created, then process **800** returns to step **806** and additional video takes are captured. For example, after a user finishes capturing Take 1 seen in FIG. 6A, the user may decide to capture another video take. The user may then repeat step **806** such that a new video take is captured (e.g., Take 2), where the selected audio track also plays while the new video take is being captured. For example, Take 2 as seen in FIG. 6B may be a second video take captured after a user has captured Take 1 of FIG. 6A. The user may capture as many additional video takes as desired. In some embodiments, a user may delete one or more video takes and/or replace one or more video takes with one or more additional video takes.

If, however, at step **808**, it is determined that the user has captured all the video takes needed to create the music video of his/her choice, then process **800** proceeds to step **810**. At step **810**, a music video is created featuring the selected audio track and at least a subset of the video takes. The subset may include any portion of any number of the video takes. For example, times 00:00-00:30, 01:30-02:00, and 03:00-03:36 of Take 3 may be used for scenes **710**, **770**, and **790** of music video **700**. Thus, in this particular example, even though images/videos may be captured for the entire duration of the selected audio track, only certain portions of captured video takes may be used for certain sections of the audio track. Similarly, times 00:50-01:00 and 01:30-02:00 of Take 2 may be used for scenes **730** and **750**.

In some embodiments, the portions of each video take used for the music video are matched with a corresponding section of the audio track based on one or more of the audio track's audio intensity, vocal phrasing, melodic phrasing, instrumental composition, tempo, and/or time signature, as well as one or more of the videos takes' video intensity, number of faces recognized therein, type of image captured within the video take, color template of the captured images within the video take, and/or any other characteristic of the video and/or audio, or any combination thereof. For example, an audio intensity of the selected audio track may be seen within waveform **760** of FIG. 7A. Sections **714**, **774**, and **794** may include low or small audio intensity levels, and therefore may be matched to portions of Take 3 having low or small video intensity levels. Sections **724**, **744**, and **784**, however, may include sections of high or large audio intensity levels, and therefore may be matched to portions of Take 1 having high or large video intensity levels. However, persons of ordinary skill in the art will recognize that any matching or pairing criteria may be used, and the aforementioned are merely exemplary.

FIG. 8B is an illustrative flowchart of a process for pairing audio tracks and video takes for a music video to be created in accordance with various embodiments. Process **850** begins, in some embodiments, at step **852**. At step **852**, a selected audio track's audio is analyzed. A user may select an audio track to be used for a music video that will be created (e.g., audio track **302b** of FIG. 3A). The audio track may then be analyzed to determine areas of high audio intensity, low audio intensity, silence, repeating melodic or vocal phrases, musical compositions, and/or specific instrumental sounds, or any other characteristic, or any combination thereof. As used herein, high and/or low audio intensity levels may correspond to any situation where the audio intensity levels exceed a certain threshold level, which in some embodiments may be set by the user, the user device, or preset prior to analysis being performed. For example, if the audio exceeds 80 dB in volume, the audio intensity may be set as high, whereas if the audio intensity is less than 40

dB, the audio intensity may be set as low. The audio intensity levels may correspond to a mean audio intensity level for a certain section of the audio track, an absolute audio intensity level, a median audio intensity level for a section of the audio track, and/or audio intensity levels of sections of the audio track as compared to other sections of the audio track. As an illustrative example, a certain section of an audio track may have an audio intensity level of 90 dBs, which may, for instance, correspond to a crash cymbal being struck within the audio track. This audio intensity level may exceed a predefined threshold for audio intensity (e.g., 80 dB), and because it exceeds the predefined threshold for audio intensity, this section may be used as a transition point for one or more video takes that will be synchronized to the audio track.

At step **854**, the audio intensity levels for the entire audio track may be determined. In some embodiments, the audio track may be broken up into sections, and each section may be analyzed sequentially or in parallel. In some embodiments, each section of the audio track may be compared with other sections of the audio track to determine whether any sections have similar audio intensity levels. For example, if a first section of the audio track has a certain audio intensity level that is substantially similar to a second section of the audio track, those two sections may be recorded as having similar audio intensity level profiles. This, in some embodiments, may correspond to a repeated section of the audio track, such as a verse phrase or a chorus for the audio track. In this way, similar transition schemas may be used for both sections.

In some embodiments, the entire audio track may be analyzed to determine an average audio intensity level at each point in the audio track (e.g., each second, millisecond, etc.). For example, each second the audio track may be analyzed to determine the audio intensity level of that particular section of the audio track. If the audio intensity level is especially high at one point (e.g., above 80 dB), then certain attributes may be placed on that section (e.g., a crash cymbal being struck). However, if the audio intensity level is particularly low (e.g., less than 40 dB), then other attributes may be placed on that section (e.g., a silent portion or rest). However, persons of ordinary skill in the art will recognize that any suitable characteristic may be applied to any section of the audio track such that a comprehensive analysis of the audio track's musical composition may be obtained.

In some embodiments, the audio intensity levels for the entire audio track may be stored in a separate log file, which may be used for pairing of the audio track with various video takes for creating the music video. For example, a log file including a time breakdown (e.g., second by second, beat by beat, etc.) and a corresponding audio intensity level (e.g., a decibel level) for that time may be created in response to the analysis of the audio track. The log file, in some embodiments, may be stored with the audio track in memory on the user device, however, in one embodiment, a new enhanced audio file may also be creating including the log file. For example, the enhanced audio file may include the audio track in its original form and the log file indicating the audio intensity level of the audio track at each point of the audio track's duration.

At step **856** of process **850**, each video take of a plurality of video takes captured by the user may be analyzed. For example, each video take may be analyzed to determine a video intensity level of each portion of the each video take (e.g., frame by frame, second by second, scene by scene, etc.). As another example, the video takes may be analyzed

to determine a number of faces that are recognized to be within each video take. As yet another example, the video takes may be analyzed to determine a geo-location where each video take was captured. Further still, each video take may be analyzed to determine a composition of each pixel

of each frame of the captured video takes, such that each frame may be compared to determine a color intensity level of each portion of the video takes.

In some embodiments, process 850 may begin at step 856 instead of at step 852. In yet some other embodiments, process 850 may begin with both steps 852 and 856 occurring in parallel with one another.

After step 856, process 850 may proceed to step 858 where video intensity levels for the captured video takes may be determined. In some embodiments, the video intensity levels may be determined for each video take of the plurality of video takes captured by the user device, however not all video takes, and not all portions of each video take may be analyzed. For example, a first video take may have video intensity levels for the entire video take determined while a second video take may only have a portion of its video intensity levels determined.

Video intensity levels, in some embodiments, may correspond to any suitable criteria for gauging the various video takes. For example, video takes including an individual dancing may be determined to have a higher video intensity level than a video take of nature scene, such as a river or ocean. As another example, video takes including a vast number of colors may correspond to a high video intensity level, whereas video takes including substantially monochrome coloring may correspond to a low video intensity level. In some embodiments, video takes including a large number of faces, or faces recognized within the video, or faces of contacts of the user capturing the video takes, may correspond to video takes having high video intensity levels. Conversely, video takes having few or no faces determined to be within the captured video takes may correspond to video takes having a low video intensity level.

In some embodiments, steps 858 and 854 may occur at a substantially same time. For example, if steps 852 and 856 are performed substantially in parallel with one another, steps 854 and 858 may be performed in parallel with one another as well. However, in other embodiments, process 850 may begin at step 852 and proceed to steps 854, 856, and 858 sequentially. Process 850 may also, in some embodiments, begin at step 856, and proceed to steps 858, 852, and 854 sequentially, or any permutation or combination thereof. Persons of ordinary skill in the art will recognize that any ordering of steps 852-858 may be implemented, and the aforementioned are merely examples.

At step 860, sections of the audio track may be paired or matched with portions of the video takes based on the determined audio intensity levels of the audio track and the video intensity levels of the video takes. For example, sections of the audio track that have a high volume level (e.g., greater than 70 dBs) may be paired with portions of a video take having high video intensity levels. As another example, sections of the audio track having a low volume level (e.g., 50 dBs or lower) may be paired with portions of a video take having low video intensity levels. In some embodiments, sections of the audio track determined to have high/low audio intensity values may cause a greater pairing weight to be placed on videos having high/low video intensity for that section of the audio track. Thus, the probability of a section of high/low audio intensity is more likely to have a corresponding portion of a video take having high/low video intensity paired together.

As an illustrative, non-limiting example, a chorus section of an audio track may have a substantially high volume level. The chorus section of the audio track may be paired with a portion of a video take or takes including a large number of faces determined to be within the video take.

FIGS. 9A-D are illustrative diagrams of user interfaces and an audio track's waveform describing techniques for synchronizing portions of video takes to sections of an audio track based on a number of faces or images determined to be within a video take in accordance with various embodiments. User interface 900 of FIG. 9A includes three (3) faces 902a-c recognized within image viewing region 906 of video take 904 (e.g., Take 1). In some embodiments, for each face recognized within viewing region 906, a corresponding outline 908a-c may appear on top of the recognized face. For example, one or more processors on a user device (e.g., processor(s) 102 of user device 100) may be capable of detecting one or more faces that are displayed on a display of the user device (e.g., display 120). For example, processor 102 of user device 100 may include one or more facial recognition modules or applications capable of determining whether one or more faces are currently displayed on display 120. In some embodiments, outlines 908a-c may also include a name of an individual recognized within viewing region 906. In some embodiments, the one or more faces may be determined to be within a video take while the selected audio track plays. In this way, the video take may be synchronized, automatically, with the audio track such that at each point in time of the audio track, an amount of faces within a video take being captured is known. Persons of ordinary skill in the art will recognize that although the aforementioned examples describe "faces" being recognized or determined within a displayed user interface, any image may be analyzed to determine whether or not any objects or items are included therein, and the use of faces is merely one particular example.

FIG. 9B shows user interface 920 including recognized faces 922a-h determined to be within video take 924 (e.g., Take 2). In some embodiments, in response to determining that faces 922a-h are being displayed within viewing region 926, outlines 928a-h may appear about each face 922a-h, respectively, such that a user viewing user interface 920 knows that the user device has recognized each face. In some embodiments, take 924 may include more faces, or may include more recognized faces than take 904 of FIG. 9A. For example, Take 2 of FIG. 9B may recognize eight (8) faces within viewing region 926, as opposed to three (3) faces within viewing region 906 of FIG. 9A.

FIG. 9C, however, shows user interface 940 including face 942, which is determined to be within video take 944 (e.g., Take 3). In some embodiments, video take 944 may display face 942 within viewing region 946, in addition to outline 948, which appears about face 942. In this particular scenario, only one face, face 942, is recognized by the user device displaying user interface 940 as being displayed within viewing region 946.

The number of faces recognized within a video take may, in some embodiments, be used as a criteria for determining which section of a selected audio track to match a portion of a video take with. In some embodiments, based on the number of faces determined to be within a displayed video take, a certain value may be assigned to that portion of the video take. For example, if a first portion of a certain video take is determined to include a large number of faces, that portion of the video take may be assigned a value corresponding to the fact that there are a large number of faces in that video. As another example, if a certain video take is

determined to include a small number of faces, that video take may be assigned a value corresponding to the fact that there are very few faces in that video.

The assigned values of each video take may then be used as a basis for matching or pairing the video takes with certain sections of the selected audio track. For example, sections of the audio track having a particularly high audio intensity value may be paired with portions of video takes that were assigned a value indicating they have a high number of faces. As another example, sections of the audio track having a particularly low audio intensity level may be paired with portions of video takes that were assigned a value indicating that they have a low number of faces.

As an illustrative example, video take **924** may be assigned a value of eight corresponding to the number of faces determined to be within Take 2. Video take **944**, however, may be assigned a value of one corresponding to the one face determined to be within Take 3. If a section of the audio track has a particularly high audio intensity level, video take **924** may be matched to that section due to the face that it has an assigned value of eight, as opposed to synchronizing video take **944** with that audio section because video take **924** has an assigned value greater than video take **944**.

FIG. 9D is an illustrative diagram of various sections of a selected audio track's waveform paired with portions of video takes based on the number of faces determined to be within each video take in accordance with various embodiments. Waveform **960** of FIG. 9D shows an exemplary waveform of a selected audio track for a music video that will be created including a subset of video takes **904**, **924**, and/or **944** paired with particular sections of waveform **960**. Waveform **960**, as seen in FIG. 9D, includes an audio intensity of the audio track over the duration of the audio track, as well as a video take **962** that will be paired with that section of the audio track. In some embodiments, only a portion of a particular video take may be paired with a particular section of the audio track, however video take **962** merely illustrates how different video takes may be matched different sections of the audio track based on an audio intensity of a section of the audio track and a number of faces recognized within a video take.

Each portion of a video take will be paired with the selected audio track for the time with the audio track that the video take is captured. In this manner, pairing of a portion of a certain video take with a certain section of the audio track may continually be aligned such that the video take is in time with the audio track. In this way, the assigned values of each video take (or each portion of a video take) may be used to pair that particular video take (or portion of the video take) to a corresponding section of the audio track.

In some embodiments, sections of waveform **960** having low or small audio intensity levels may be matched with portions of video takes **904**, **924**, and **944** which have a relatively low or small number of faces recognized therein, or a low or high value assigned to the video takes based on the number of faces recognized therein. For example, sections **970a** of waveform **960** may be paired with video take **944**. Sections **970a**, in one embodiment, correspond to sections of the selected audio track having a relatively low or small audio intensity level. Thus, these sections **970a** are paired with video take **944** having a substantially low or small number of faces recognized therein, such as singular face **942**.

In some embodiments, sections of waveform **960** having a high or large audio intensity level may be paired with portions of video takes **904**, **924**, and **944** having relatively

high or large numbers of faces recognized therein. For example, section **970c** of waveform **960** may have a substantially high audio intensity level. Thus, section **970c** may be paired with video take **924** having eight (8) faces **922a-h** recognized therein.

In some embodiments, sections of waveform **960** having audio intensity levels higher than that of sections **970a**, but lower than section **970c**, may correspond to sections having a medium level of audio intensity. For example, sections **970b** may correspond to a verse portion of a selected audio track. In some embodiments, because sections **970b** have a medium level of audio intensity, video take **904** having three (3) faces recognized therein may be synchronized to section **970b**.

Persons of ordinary skill in the art will recognize that any take including any number of faces may be paired with any section of an audio track, and the aforementioned is merely exemplary. Furthermore, persons of ordinary skill in the art will recognize that any object may be recognized within a captured video take, and faces are merely one object or item that may be recognized. Various other types of recognizable objects or items include, but are not limited to, bodies of individuals, faces of only contacts of a user, animals, geographical landmarks or GPS locations, pixel intensity, frequency of a corresponding video signal, or any other suitable object/item, or any combination thereof.

FIG. 9E is an illustrative flowchart of a process for pairing video takes to an audio track based on a number of faces determined to be within the video takes in accordance with various embodiments. Process **980** of FIG. 9E may, in some embodiments, begin at step **982**. At step **982**, an audio track is selected. For example, an audio track, such as audio track **302b** of FIG. 3B, may be selected by a user. The audio track may be stored on a user device, external device, or music server, for example.

At step **984**, a plurality of video takes may be captured by the user. In some embodiments, the selected audio track may play through one of the user device's audio outputs (e.g., speakers **122**) while the plurality of video takes are captured using one or more of the user devices image capturing components (e.g., cameras **112**). The captured video takes may be of any duration, and may include any suitable content such as one or more individuals, one or more scenic backgrounds, and/or animated videos, for example. In some embodiments, steps **982** and **984** of FIG. 9E may be substantially similar to steps **802** and **804** of FIG. 8A, and the previous description may apply.

At step **986**, a number of faces within each video take captured may be determined. For example, if a first video take, such as Take 1 of FIG. 9A, includes three (3) faces, one or more facial recognition modules resident on the user device may create a corresponding outline around each individual's face. The outlines, such as outlines **908a-c** of FIG. 9A, allow a user to visualize the number of faces that have been recognized within the captured video take. In some embodiments, the number of faces determined to be within a video take may only include faces corresponding to contacts of a user operating a user device capturing the video take(s). For example, contact information including a contact's photograph may be stored in memory **104** of user device **100**. When a face appears within a captured video take that is substantially similar to a face recognized within a certain contact's photograph, that face will be recognized by the user device as being within the captured video take. However, in other embodiments, the captured video take may recognize any and all faces within any number of video takes. Furthermore, in at least some embodiments, other

objects or images may be recognized within a video take (e.g., landmarks, bodies, pets, etc.) and the use of detecting one or more faces within a captured video take is merely one example.

The determination of the number of faces within a video take may occur, in some embodiments, at a substantially same time as the capturing of the video take(s). For example, as the video take is captured, the number of faces within the video take is determined at each point in time of the audio track. In this way, the number of faces within the video take is known prior to any pairing occurring. Furthermore, each video take is synchronized to the audio track such that the number of faces determined to be within each portion of a video is known, and which section of the audio track is playing for that portion of the video take is also known.

In some embodiments, a value may be assigned to each video take based on the number of faces determined to be within that video take. For example, Take 2 of FIG. 9B may be assigned a value of eight (8) based on the eight (8) faces determined to be within Take 2. As another example, Take 3 of FIG. 9C may be assigned a value of one (1) based on the one (1) face determined to be within Take 1.

In some embodiments, portions of a video take may be assigned different values based on a different number of faces determined to be within each portion of the video take. For example, in a first portion of a video take, three (3) faces may be determined to be present, and the first portion may be assigned a value of three (3). However, at a second portion of the video take, twelve (12) faces may be determined to be present, and the second portion may then be assigned a value of twelve (12).

In some embodiments, the assigned value of each video take, or portion of a video take, may correspond to whether that particular video take includes a number of faces greater or less than a certain threshold value. For example, a first threshold may be set at there being one (1) face within a video take, whereas a second threshold and a third threshold may be set at two (2) faces and five (5) faces being within a video take. Each threshold may be assigned a value of low, medium, and high, respectively, corresponding to the number of faces present within that video take. In this particular example, Take 3 of FIG. 9C may be assigned a value of low as only one (1) face is present, Take 1 of FIG. 9A may be assigned a value of medium as more than two (2) but less than five (5) faces are present, and Take 2 of FIG. 9B may be assigned a value of high as more than five (5) faces are present.

At step 988, a subset of the plurality of captured video takes may be paired to the selected audio track based on the determined number of faces within the video take. In some embodiment, video takes, or portions of video takes, having a certain assigned value may be paired to section of the selected audio track having a complimentary or corresponding audio intensity level. For example, as described above, various sections of the selected audio track may be determined to have a low, medium, and/or high volume level. These audio intensity values may correspond to the various sections of the audio track (e.g., a verse may have a medium volume level, a chorus may have a high volume level). In some embodiments, if the assigned value for a particular video take is a certain value, then that video take may be paired to a specific section of the audio track. For example, if there are a large number of faces determined to be within the video take (e.g., Take 2), then that video take may be assigned a high audio intensity value, and may be paired to a section of the audio track having a high audio intensity (e.g., a chorus section). As another example, if the number

of faces within a video take is low (e.g., Take 3), then that section may be paired to a section of the audio track having a low audio intensity (e.g., an instrumental section).

In some embodiments, as mentioned above, each video take may have various portions that are assigned different values. In this particular scenario, portions of different audio takes may be paired to sections of the selected audio track based on which assigned value of a portion of a video take best matches a certain section of the audio track. For example, if only a first portion of a first video take has an assigned value of high video intensity, that portion may be paired to the section of audio track having high audio intensity. In this way, the subset of video takes may include various portions of some or all of the captured video takes such that the most appropriate portions of video takes are paired to the most appropriate sections of the audio track.

At step 990, a music video is created. The created music video includes the subset of video takes (e.g., the portions of the video take or takes determined at step 990), and the selected audio track. The music video, in one embodiment, combines the various video takes and the selected audio track into one synchronized item that may be enjoyed by the user, shared by the user, published by the user, and/or modified by the user.

FIGS. 10A-D are illustrative diagrams of various vocal and melodic indicators and phrases for use as transition points between video takes for a music video synchronized to an audio track in accordance with various embodiments. FIG. 10A includes waveform 1000. In some embodiments, waveform 1000 includes wave 1002, which may repeat after a time d1. For example, wave 1002 may correspond to a bass, or bass beat, which is played within an audio track every measure of the audio track, for instance the first quarter note of each measure. Thus, time d1 corresponds to an amount of time between the first quarter note of each measure of waveform 1000 for a selected audio track.

In some embodiments, each time wave 1002 occurs, a transition between a portion of a video take and another portion of another video take may occur. For example, if wave 1002 corresponds to a bass drum that repeats after a time d1, at each instance of wave 1002 a different portion of a video take may be used for a music video. Thus, various portions of various video takes capture by the user may be paired with an audio track based on one or more occurrences of a particular sound, such as wave 1002.

FIG. 10B includes waveform 1020. Waveform 1020 may, in some embodiments, include waves 1022 and 1024. Wave 1022 may repeat after a time l, while wave 1024 may repeat after a time d2. Each of waves 1022 and 1024 may correspond to different sounds of audio levels. For example, waves 1022 may correspond to a soft, frequently repeating sound, such as a tambourine or maraca. Wave 1024, on the other hand, may correspond to a louder sound, such as a cymbal crash or a guitar strum, that repeats after a certain number of tambourine or maraca, for example, sounds.

In some embodiments, a phrase may include both waves 1022 and 1024. For example, a repeating instrumental phrase may include wave 1022 repeating a first number of times, followed by wave 1024. The instrumental phrase may be of duration d2, which itself includes waves 1022 repeating after time l.

Similar to how various portions of various video takes may be paired to wave 1002 of waveform 1000, portions of video takes may be paired to portions of waveform 1020 based on occurrences of wave 1022 and/or 1024. For example, in response to wave 1024 occurring, a portion of a video take having a high or large video intensity, or

multiple faces recognized therein, may be cut to for a music video. As another example, in response to wave form **1022** occurring, a portion of a video take having a low or small video intensity, or few faces recognized therein, may be cut to. In some embodiments, cutting to various portions of video takes may only occur in response to waves exceeding a certain threshold. For example, an occurrence of wave **1024** may trigger a cut to a portion of a video take, whereas when wave **1022** occurs, no change or cut in the video take being presented may occur.

FIG. **10C** includes waveform **1040**. Waveform **1040**, in some embodiments, includes waves **1042** and **1044**. Wave **1042**, in one embodiment, is a wave having a large peak and a short tail, while wave **1044** is a wave have a smaller peak and a longer tail with respect to wave **1042**. These two waves may, for example, correspond to certain types of sounds within waveform **1040**, such as a crash cymbal or a bass drum. A crash cymbal, for example, is a percussion instrument having a very high audio intensity sound when struck (e.g., greater than 100 dB), which decreases in intensity fairly quickly after the initial strike. A bass drum, on the other hand, may have a lower audio intensity (e.g., less than 80 db) when struck than a crash cymbal, however the intensity of the sound may decrease less quickly than that of the crash cymbal. Persons of ordinary skill in the art will recognize that the use of a crash cymbal and a bass drum are merely exemplary, and any suitable sound or instrument may be used to describe waves **1042** and **1044**, and the aforementioned merely are one illustrative scenario of two instruments with suitable waveforms (e.g., high peak-small tail, short peak-long tail).

In some embodiments, different portions of different or similar video takes may be paired to a particular wave or sound based on that particular wave or sound's intensity and/or tail. For example, different video takes may be cut to in response to each occurrence of a crash cymbal. Thus, each time wave **1042** occurs, the music video may cut to a different video take (e.g., Take 1, Take 2, etc.). As another example, each time a bass drum occurs, a different portion of a same video take cut to previously due to the occurrence of a crash cymbal, may be cut to. Thus, in response to wave **1042** occurring, a music video may cut from Take 2 to Take 3, and then in response to wave **1044** occurring after wave **1042**, a different portion of Take 3 (e.g., times 00:50-01:20) may be cut to. In this way, a music video, such as music video **700** of FIG. **7A**, may be created based on the various types of waves or sounds within a particular audio track used to synchronize with the music video.

FIG. **10D** includes waveform **1060**. Waveform **1060** includes, in one embodiment, wave packet **1062**. Wave packet **1062** may correspond to a repeating wave of audio that has a duration of time  $t_1$  and repeats after a time  $t_2$ . As an illustrative example, wave packet **1062** may correspond to a vocal phrase of length  $t_1$  (e.g., the duration of time of the vocal phrase is length  $t_1$ ), where the vocal phrase repeats periodically during waveform **1060**. The period of the vocal phrase repeating is, for example, time  $t_2$ .

In some embodiments, cuts or transitions to various portions of various video takes may occur in response to wave packet **1062** occurring during an audio track. For example, in response to wave packet **1062** being detecting within the audio track, or waveform **1060**, a transition from a certain portion of Take 1 to another portion of Take 2 may occur. As an illustrative example, in response to wave packet **1062** occurring, the created music video may have scene **720**, including Take 1 at times 00:15-00:35, switch to scene **730**, including Take 3 at times 00:40-00:50. In this way,

video takes may be paired with an audio track based on one or more instances of a repeating vocal phrase or a standalone vocal phrase.

FIG. **10E** is an illustrative flowchart of a process for generating a music video including various video takes paired to a recorded audio track based on a determined vocal and/or melodic phrase within the audio track in accordance with various embodiments. Process **1080** begins at step **1082**. At step **1082**, an audio input is received via an audio input interface. For example, a user may receive an input from an external device, such as an electric guitar or keyboard, plugged into their user device via an external device input (e.g., external device input **116**). In some embodiments, the audio input may be received via one or more microphones resident on the user device. For example, a user may record themselves singing or playing an acoustic guitar via microphone(s) **114** located on user device **100**.

At step **1084**, the received audio input may be recorded on the user device. For example, user device **100** of FIG. **1** may include memory **104** and/or storage **106**, which may store any audio recorded by user device **100** (e.g., via microphone(s) **114** and/or external audio input **116**). In some embodiments, one or more audio recording modules or programs may run on the user device which, in response to a user input, may begin the recording process allowing the user device to record. In some embodiments, a user may record one or more audio inputs onto an external medium, such as a mixing board or personal recorder, and may load the recorded audio to the user device. Persons of ordinary skill in the art will also recognize that steps **1082** and **1084** may be performed at a substantially same time. In some embodiments, however, no audio may be recorded and an audio track may be selected to be used, similar to step **802** of FIG. **8A**.

At step **1086**, a determination may be made by one or more processors on the user device that the recorded audio includes a vocal phrase and/or a melodic phrase. For example, an audio analysis module or program resident on the user device may analyze the recorded audio and may detect one or more vocal phrases or one or more melodic phrases within the recorded audio. Vocal phrases, for instance, may correspond to catchphrases, lyrics, exclamations, or any other vocal characteristic that may be recognized by the audio analysis module which, when played, allow a user to recognize the particular audio track being played. Melodic phrases, for instance, may correspond to a riff, catchphrase, melody, and/or hook, which when played, allow a user to recognize the particular audio track being played. Vocal phrases and melodic phrase differ merely in that melodic phrases, as used herein, may not include spoken words while vocal phrases do, however this is merely exemplary.

At step **1088**, at least a portion of at least one of a plurality of captured video takes may be paired to the recorded audio based on the determined vocal phrase and/or melodic phrase. For example, as seen above with respect to step **988** of FIG. **9E**, based on the video intensity of a particular portion of a video take, a section of audio may be paired with that video take. In one illustrative example, a portion of a video take including a large number of faces recognized therein (e.g., Take 2 of FIG. **9B**) may be paired with a recognized vocal or melodic phrase corresponding to a chorus of a particular audio track. The vocal or melodic phrase may be recognized by the audio analysis module as being a chorus section of the audio track, and as such, may be synchronized to a portion of one of the video takes including a high video intensity value. As another illustrative

25

tive example, a section of the recorded audio corresponding to a verse section may be synchronized with a portion of a video take including few faces recognized therein (e.g., Take 1 of FIG. 9A). Similarly, a section of the audio determined to be an instrumental section only may be synchronized with a portion of a video take including one or no faces determined to be therein (e.g., Take 3 of FIG. 9C).

The plurality of video takes may, in some embodiments, be captured prior to the pairing occurring. For example, video takes may be captured prior to, in parallel to, or after the determination of whether the vocal or melodic phrase is within the recorded audio. In some embodiments, process 1080 may include an additional step which may be substantially similar to step 806 of FIG. 8A, and the previous description may apply.

At step 1090, a music video may be generated. The generated music video, in some embodiments, may include the recorded audio track and at least the portion of the at least one of the plurality of captured video takes synchronized to the recorded audio track. Thus, a music video synchronized with various sections of the recorded audio may be created that is both professional in appearance and quality.

FIG. 11 is an illustrative diagram of a user interface for recording an audio track to be used for creating a music video in accordance with various embodiments. User interface 1100 may include tempo indicator 1102, musical key indicator 1104, recording waveform 1106, and record button 1108. Other options may be displayed within user interface 1100, such as an edit button, a pause or stop recording button, a musical portion (e.g., verse, chorus) button, a time signature indicator, and/or a musical instrument selection button. However, for simplicity and clarity, only tempo indicator 1102, musical key indicator 1104, recording waveform 1106, and record button 1108 are shown within user interface 1100.

Tempo indicator 1102 may, in some embodiments, show and/or set a tempo for the audio track that will be recorded. Tempo indicator 1102 may include a metronome that plays an audible sound (e.g., a click, beep, or cowbell) or visual indicator (e.g., a flashing light, blinking light, etc.) at a certain rate to indicate to the user making the audio recording a tempo for that recording. For example, the user may set tempo indicator 1102 to be sixty (60) beats per minute (“Bpm”), which means that sixty audio tones will be evenly outputted over the course of a minute (e.g., one beat every second). In some embodiments, one or more processors 102 on user device 102 may be capable of determining a tempo of the recorded audio track based on the audio recording. For example, after a user has recorded an audio track on their user device, the user device may analyze a waveform (e.g., waveform 360 of FIG. 3B) of the recorded audio track to determine a tempo of the audio track based on the audio intensity levels of the waveform.

Musical key indicator 1104, in some embodiments, may be set by the user prior to recording an audio track. For example, the user may set musical key indicator 1104 to be in the key of A-minor. If any of the notes or vocals of the audio recorded by the user device do not match up with the desired musical key, the user device may notify the user. In some embodiments, the user may be prompted to re-record one or more sections of the audio track to fix any tonal issues, or the user may choose to leave the off key sections. In one embodiment, the user may be able to instruct their user device to perform an auto-tune function on the recorded audio to force any section of the recorded audio track that is

26

not in-tune to the selected musical key, to be adjusted so that it conforms with the selected musical key.

In some embodiments, recording waveform 1106 may show a waveform of some or all of the audio track being recorded. The user may then be able to see areas of the recorded audio track where the audio intensity is particularly high, low, or consistent, for example. In some embodiments, recording waveform 1106 may also include visual indicators of the tempo of the song based on the selected tempo of tempo indicator 1102. This may allow a user to synchronize their recording with the desired tempo. Synchronizing the audio with a tempo may be extremely useful when creating a music video that is to be synchronized with the audio track because transition points between various portions of video takes will be more clearly defined than if the audio is not in sync with the desired tempo.

Record button 1108 may, in some embodiments, be substantially similar to capture button 602 of FIG. 6A with the exception that the former may correspond to capturing audio only. However, in some embodiments, a user may be able to press record button 1108 again after starting the audio recording processes to pause and/or stop the recording. Furthermore, record button 1108 may be pressed another time to start recording the audio track again.

In some embodiments, after a music video has been created, one or more options to share the music video may be presented to the user. For example, an option to upload the created music video to a website, or a linked may be provided a website where the music video may be viewed. In some embodiments, an option to share the music video via one or more of email, SMS or text message, instant message, or on one or more social media networks may be provided. In some embodiments, an option to save the music video to the user devices memory or storage (e.g., memory 104 and storage 106) may be provided.

It should be appreciated that the various embodiments described above can be implemented by software, but can also be implemented in hardware or a combination of hardware and software. The various systems described above can also be embodied as computer readable code on a computer readable medium. The computer readable medium can be any data storage device that can store data, and that can thereafter be read by a computer system. Examples of computer readable mediums include read-only memory, random-access memory, CD-ROMs, DVDs, magnetic tape, and optical data storage devices. The computer readable medium can also be distributed over network-coupled computer systems so that the computer readable code is stored and executed in a distributed fashion.

The above described embodiments of the invention are presented for purposes of illustration and not of limitation.

What is claimed is:

1. A method for creating a music video in which a plurality of video takes is synchronized to an audio track, the method comprising:
  - selecting an audio track;
  - capturing a plurality of video takes;
  - synchronizing each video take of the plurality of captured video takes with the selected audio track while each video take of the plurality of video takes is being captured, wherein synchronizing further comprises playing, from a first beginning, the selected audio track at substantially the same time as a second beginning of capturing each video take of the plurality of video takes; and

27

creating a music video comprising:  
the selected audio track; and  
at least a subset of the plurality of video takes comprising at least two video takes of the plurality of video takes synchronized with the selected audio track.

2. The method of claim 1, wherein synchronizing further comprises:  
synchronizing each video take of the plurality of captured video takes with the selected audio track based on at least one of:  
an audio intensity of the audio track; and  
a video intensity of the plurality of video takes.

3. The method of claim 1, wherein the plurality of video takes are captured using a user device.

4. The method of claim 3, wherein the user device comprises at least one image capturing component.

5. The method of claim 1, wherein creating further comprises:  
extracting portions of each take of the plurality of captured video takes to be used for sections of the selected audio track, the extracted portions forming the subset of the plurality of video takes.

6. The method of claim 1, wherein the audio track is stored on at least one of:  
a user device;  
a music server; and  
an external device.

7. The method of claim 1, further comprising:  
playing the selected audio track while each video take of the plurality of video takes is captured.

8. The method of claim 1, wherein selecting further comprises:  
determining an amount of time of the selected audio track to be used.

9. The method of claim 8, wherein the created music video has a duration equal to the determined amount of time of the selected audio track.

10. The method of claim 1, wherein creating further comprises:  
selecting the subset of the plurality of video takes; and  
determining an arrangement of the subset of the plurality of video takes with respect to the selected audio track.

11. A user device, comprising:  
at least one audio input component;  
at least one image capturing component;  
memory for storing: an audio track recorded by the at least one audio input component and a plurality of video takes captured by the at least one image capturing component; and  
at least one processor operable to:  
determine, within the recorded audio track, at least one of a vocal phrase and a melodic phrase; and  
synchronize each video take of the plurality of captured video takes to the recorded audio track as each video take of the plurality of video takes is being captured, wherein synchronizing further comprises playing, from a first beginning, the selected audio track at substantially the same time as a second beginning of capturing each video take of the plurality of video takes; and  
create a music video comprising the recorded audio track and a portion of the plurality of captured video takes, wherein creating comprises:

28

displaying the portion based on at least one of the determined at least one vocal and one melodic phrase.

12. The user device of claim 11, wherein the at least one audio input component comprises at least one of:  
a microphone operable to receive audio signals; and  
a musical instrument input operable to receive audio signals from a musical instrument.

13. The user device of claim 11, wherein the at least one vocal phrase comprises at least one of:  
a repeated word;  
a repeated phrase of words; and  
a repeated vocal phrase.

14. The user device of claim 11, wherein the at least one melodic phrase comprises at least one of:  
a repeated instrumental phrase; and  
a repeated percussion rhythm.

15. The user device of claim 11, wherein the at least one processor is further operable to:  
determine a beginning and an ending for at least one of the vocal phrase and the melodic phrase.

16. The user device of claim 15, wherein at least the portion of the plurality of video takes comprises at least a first portion of a first video take and a second portion of a second video take, the at least one processor is further operable to:  
create a music video to be created wherein a transition between the first portion of the first video take and the second portion of the second video take occurs at the beginning of the at least one of the at least one vocal phrase and the at least one melodic phrase.

17. A method for creating a music video, comprising:  
selecting an audio track;  
capturing a plurality of video takes;  
determining a number of faces within each video take of the captured plurality of video takes while each take of the plurality of video takes is being captured;  
synchronizing, while the plurality of video takes are being captured, each video take of the plurality of captured video takes to the selected audio track, wherein synchronizing further comprises playing, from a first beginning, the selected audio track at substantially the same time as a second beginning of capturing each video take of the plurality of video takes; and creating a music video comprising the selected audio track and at least a subset of the plurality of captured video takes synchronized to the selected audio track; wherein creating comprises:  
displaying the subset of the plurality of captured video takes based on the number of faces determined to be within each video take.

18. The method of claim 17, further comprising:  
determining, based on a melodic composition of the selected audio track, a verse and a chorus of the audio track.

19. The method of claim 18, wherein creating further comprises:  
aligning at least a first portion of the subset of the plurality of captured video takes to one of the determined verse and the determined chorus of the audio track based on the determined number of faces.
